SIR,—Prolapsus uteri is nothing but a hernia, and therefore subject to the rule which applies to the treatment of hernia wherever it occurs—namely, the proper closure of the aperture or ring through which the intra-abdominal structures protrude by an adequate reconstruction of the impaired parietal wall or surface. How to do this effectually has exercised the mind of every gynæcologist. Plastic operations, however carefully and extensively performed, fail in a fair proportion of cases to prevent visceral extrusion, and especially the recurrence of the cystocele; hence the advent of the interposition operation. I agree with Dr. Blair Bell that the latter gives excellent results, impaired by the fact that sepsis, due to defective sterilisation of the uterine and cervical mucous surfaces, sometimes complicates convalescence. But the interposition operation is at the best a makeshift. The correct way to stop a hole in a wall is not by shoving a plug through the aperture. I have seen women, some operated upon by others, some by myself, where the "bouchon utérin," as the French call it, protruded behind an overstretched perineum.

I believe that the only effective way to treat procidentia uteri is a reconstruction of the whole of the pelvic floor from above downwards, including the peritoneum, the subjacent mass of fibro-muscular and adipose tissue forming the base of the broad ligaments, the muscular and fibrous slings underlying these, and, finally, the vaginal outlet, together with the skin covering the perineum. Dr. Blair Bell has attempted this by bringing together intra-peritoneally the utero-sacral ligaments, obliterating Douglas's pouch, slinging upwards the whole visceral pelvic floor, limiting its downward distensibility and declivity, the whole combined with plastic operations. Hence his large percentage of successes. But the same results can be obtained without opening the abdomen. The operation is not as elegant and easy as if done by laparotomy, but it is equally successful. It simply consists in extending the colpo-perineorrhaphy right up to Douglas's pouch, opening the latter, and then by means of a curved needle with silk ligature bringing together the two utero-sacral ligaments, as well as the base of the broad ligaments, thus obliterating Douglas's pouch from below. This operation is no new thing; it was described long ago in America as the correct way of treating uterine deviations. It corrects these, while at the same time it arrests any tendency to descend. In severe procidentia, especially that occurring after the menopause, it is advisable to sacrifice the uterus. The operation is then still easier; not only the utero-sacral ligaments but the whole of the base of the broad ligaments are sewn up in one firm bunch. This, coupled with a myorrhaphy of the levator ani and an extensive anterior and posterior colpo-perineorrhaphy, invariably gives good results, even in the worst cases.

I am, Sir, yours faithfully,
G. A. CASALIS DE PURY,
Late Consulting Gynæcologist to the Victoria Hospital, Winburg, Cape.
Wimpole-street, W.

SINCERE FLATTERY

To the Editor of THE LANCET

SIR,—The Executive Council of the Federation of Medical and Allied Societies recently invited the Council of the British Medical Association to reopen the conferences held between various medical bodies in the summer of 1919 The organisations which took part in those conferences were the British Medical Association, the Federation of Medical and Allied Societies (then the Medical Parliamentary Committee), the Medical Women's Federation, the Medico Political Union, and the Association of Panel Committees At the final conference it was agreed "that the members of the conference should report the findings to their constituent bodies, *and that the calling of a further conference should* depend on the attitude taken by those bodies'

In accordance with the terms of this agreement, and after ascertaining that four of the five bodies concerned desired it, my Executive Council wrote to the British Medical Association on March 23rd, 1920, and the *following reply, dated May* 28th, 1920, has been received —

British Medical Association 429 Strand W C 2

DEAR SIR —Your letter of March 23rd was placed before the Council of the Association at its meeting on the 19th inst when I was instructed to say that the Council sees no useful purpose in reopening the former conferences The Council is recommending to the Representative Body the widening of the constitution of the Association so as to allow it to offer federation or affiliation to *medical bodies which care to enter into such relations with the* Association If these recommendations are accepted by the Representative Body it is proposed later in the year to hold conferences with medical societies representing sectional interests with a view to determining how best to carry these proposals for affiliation or *federation into effect* Yours faithfully

(Sd) ALFRED COX Medical Secretary

It would appear that the Council of the Association has in contemplation the possibility of reconstructing itself on the lines of this Federation

I am, Sir, yours faithfully,

N HOWARD MUMMERY,

General Secretary Federation of Medical and Allied Societies
5 Vere street Cavendish square W May 31st 1920

*** We continue to hope that the British Medical Association will find a way to coöperate with the Federation of Medical and Allied Societies in the common object of unifying the aims of medicine and the public for useful legislation in the future —ED L

UNIVERSITY OF CAMBRIDGE —The State Medicine Syndicate recommend that a University Lectureship in *Medical Radiology and Electrology should be instituted for* a period of five years from June 1st 1920

UNITED SERVICES MEDICAL SOCIETY —A general meeting of this society was held at the Royal Army Medical College on May 28th when it was resolved that the society should amalgamate with the War Section of the Royal Society of Medicine on the condition that its members were accepted without entrance fee to the section but subject to an annual fee of one guinea The society decided to hand over to the Royal Society of Medicine the balance of cash as shown on the books on Jan 1st, 1915 the remainder to be divided amongst the subscribers to the society since that date To permit of this adjustment it is requested that the subscribers in question will forward their present addresses to Major E M Middleton the secretary of the United Services Medical Society, at the Royal Army Medical College Grosvenor road S W

WEST LONDON MEDICO CHIRURGICAL SOCIETY —An ordinary meeting of this society will be held to-day Friday, at 8 30 P M in the society's rooms West London Hospital Dr Herbert Chambers the *President in the chair* A paper will be read by Dr Ernest Snowden entitled 'A Short Method of Psychological Analysis'

The Cavendish lecture will be given by Professor C S Sherrington on 'Posture' and a conversazione will be held at the Kensington Town Hall on Friday June 25th Members desiring tickets for guests are requested to communicate at once with the senior honorary secretary Dr J J Halls Dally 93 Harley street, London, W 1

FLECHSIG'S JUBILEE —On May 23rd the well known Leipzig anatomist and psychiatrist, Paul Flechsig celebrated the fiftieth anniversary of his graduation Born at Zwickau in 1847, he attended the gymnasium there going on to study medicine in Leipzig When assistant at the University Physiological Institute his first considerable work on Conduction Paths in the Brain and Spinal Cord attracted the attention of his master Ludwig whose influence with that of Kussmaul and Meynert brought Flechsig within two years of his graduation to the rank of professor In 1882 he took over the Neurological Clinic built and furnished on plans drawn up by himself whose chief he still is Flechsig holds an honorary doctorate in the Faculty of Exact Sciences at Oxford and is an honorary member of learned societies in Dorpat Dresden Florence Kieff London Munich Paris Petrograd Rome and Vienna On the day of his jubilee the firm of Georg Thieme of Leipzig issued as a Festschrift the first volume of a monumental work on the Anatomy of the Human Brain and Spinal Cord on a Myelogenetic Basis on which the veteran psychiatrist has been intensively engaged for ten years

A RECENT flag day held by the League of the Roses, Miss M. F. Roby chairman, realised £326 18*s.* 5*d.* for the Great Northern Central Hospital.

Sir Robert Borden, the Prime Minister of the Canadian Parliament, has written to Mr. Rockefeller expressing the appreciation of the Canadian people for his gift of $5,000,000 to Canadian medical education.

THE first annual conference of the subassistant surgeons of Madras Presidency was held recently at the Madras Medical College, Major-General Giffard, Surgeon-General with the Madras Government, presiding. About 200 subassistant surgeons from the city attended.

Dr. John O'Conor, senior medical officer of the British Hospital, Buenos Ayres, has been appointed a Knight Commander of the Most Excellent Order of the British Empire for services in connexion with the war.

INDIAN MEDICAL SERVICE DINNER.—The annual dinner of the Indian Medical Service will be held at the Trocadero on Tuesday, June 8th, at 7.45 P.M., Major-General G. F. A. Harris, C.S.I., in the chair. Tickets and all particulars may be obtained from the joint honorary secretary, Colonel J. J. Pratt, I.M.S. (retired), 63, Addison-road, London, W. 14.

THE Board of Governors of the American Hospital in London are giving a dinner at Claridge's Hotel on July 6th, at which the guest of the evening will be Dr. Charles W. Mayo, of Rochester, U.S.A. The American Ambassador, Lord Bryce, and Lord Reading are associated with the hosts of the dinner, and Mr. Philip Franklin, 27, Wimpole-street, W., is acting as honorary secretary.

Dr. Addison has appointed Mr. Llewelyn Williams, M.C., to be Medical Member of the Welsh Board of Health with the status of a Senior Medical Officer of the Ministry of Health. Dr. Meredith Richards, who has been acting temporarily as medical member of the Welsh Board of Health, has been appointed to the headquarters establishment of the Ministry of Health.

IMPERIAL WAR MUSEUM AND GREAT VICTORY EXHIBITION.—The opening ceremony of the above exhibition will be held at the Crystal Palace on Wednesday, June 9th, at 11.15 A.M., when the King will preside. We learn that the war exhibits are of a most interesting and varied character, and should occupy the visitor's attention for some time. Medical men will be attracted, amongst other sections, to the Naval Medical Section, organised by Surgeon-Commander M. H. Knapp, R.N. Altogether the exhibition promises to be a great national event.

A LIST OF SPECIAL SCHOOLS.—The Board of Education has just issued a list of special schools for blind, deaf, and defective children in England and Wales, with a note as to the amount of accommodation and average attendance. As this list is intended solely for official use the schools are entered under the county in which they are situated without an indication of the authority responsible for them. It appears that in England 39 day and 19 residential schools are provided for the blind, 29 day and 20 residential for the deaf, 171 day and 20 residential for the mentally defective. Schools for tuberculous and non-tuberculous children are classified together. It is interesting to note that London contains more than one-third of the day schools for blind, deaf, and physically defective children.

A HOLIDAY COURSE IN TUBERCULOSIS.—A holiday course, under the auspices of the Assistance Publique of Paris, will be held from July 19th to 31st, each day at 2 P.M., at the Maritime Hospital at Berck-sur-Mer (Pas-de-Calais). It will consist of 12 lessons on osteo-articular and ganglionic tuberculosis and some elements of practical orthopædics by the following medical men: M. Menard, honorary chief surgeon of the Maritime Hospital; M. Sorrel, chief surgeon; MM. Andrieu and Tridon, assistant surgeons; M. Mozer, chief of the hospital laboratory; M. Parin, chief of the laboratory of radiology of the hospital. The course will comprise the elements of diagnosis furnished by the laboratory and radiology, Pott's disease, coxalgia, tuberculosis of the knee and tarsus, tuberculosis of the shoulder, elbow, and wrist, tuberculous osteitis, non-tuberculous osteitis and chronic osteo-arthritis with their clinical and laboratory diagnoses, chronic adenitis, helio-marine, radiotherapeutic and surgical treatment, rickets and its treatment, deformities and osteo-articular troubles of adolescence, scoliosis and its treatment. The mornings will be devoted to practical demonstrations as follow: Clinical examinations on Mondays, operations and punctures on Tuesdays and Fridays, plasters Wednesdays and Saturdays, laboratory demonstrations Thursdays. The fee for the course is 150 francs (Internes of the Paris hospitals are exempt). Enrolment should be made by letter addressed to Dr. Parin, Hôpital Maritime, Berck-Plage (Pas-de-Calais), France.

EAST SUSSEX HOSPITAL.—The governors of the East Sussex Hospital at Hastings have elected Dr. H. Stanley, Mr. J. W. M. King, and Mr. H. Groome as the first honorary life governors in recognition of valuable work in the interests of the institution.

ROYAL DEVON AND EXETER HOSPITAL.—As a result of the appeal for £20,000 for the extension of the Royal Devon and Exeter Hospital the sum of £12,622 has been received, and it is hoped that the remaining amount will be shortly subscribed.

DEVON AND CORNWALL EAR AND THROAT HOSPITAL, PLYMOUTH.—At the annual meeting of the subscribers to this institution held on May 28th it was reported 1014 patients had been treated compared with 760 in 1918. The financial statement showed a deficit of £100. The chairman, the mayor, alluded with regret to the retirement of Mr. C. E. Bean, who had been honorary surgeon to the hospital since its foundation 33 years ago, and paid a tribute to the value of his services.

THE LATE MR. W. EAGER.—Wilson Eager, L.R.C.P., M.R.C.S., L.S.A., died at his residence, Woodbridge, Suffolk, in his seventy-sixth year. The deceased was a son of the late Mr. R. Eager, a surgeon, of Guildford. He was for 27 years medical superintendent of the Suffolk County Asylum, Melton, now known as St. Audry's Mental Hospital. He resigned in 1897, and joined his elder brother at Northwoods Private Asylum, near Bristol; ten years later he retired from active work, and went to live at Woodbridge, Suffolk, where he was highly esteemed. His son, Dr. Richard Eager, is deputy medical superintendent of the Devon Mental Hospital.

BRITISH WATERWORKS ASSOCIATION.—The ninth annual general meeting of this association will be held in the Council Chamber, The Exchange, Nottingham, on Thursday, July 1st. The proceedings include the reading and discussion of interesting papers on water undertakings from both the economic and hygienic point of view, and the members of the association and their friends are invited to visit the filtration plant and pumping stations belonging to the Nottingham corporation. The sources of water-supply in Nottingham are manifold, including the moorland area of the Derwent Valley, the deep wells in sandstone at Bestwood and Boughton, and the artesian boreholes at Burton Joyce. The meeting altogether promises very interesting proceedings.

MATERNITY HOME FOR SAILORS' WIVES.—The Central Commtitee of the Navy League has given £30,000 for the establishment of maternity homes for the wives of sailors and Marines at each of the three principal naval ports—Portsmouth, Devonport, and Chatham—£10,000 for each port. In 1917 the women of Canada collected a handsome sum as an expression of their admiration for the British Navy. Of that money £3000 were handed over to the Commander-in-Chief at Portsmouth for maternity purposes. A meeting to inaugurate a scheme for its application was held in the Town Hall, Portsmouth on May 26th, when it was stated that a suitable house in Southsea had been purchased for £4000 and was being equipped as a maternity home. The plans have now received the official approval of the Ministry of Health. The institution of the home has the support of all ranks and ratings in the navy.

TUBERCULOSIS IN ABERDEENSHIRE.—Dr. H. J. Rae, the tuberculosis officer for the county of Aberdeen, has completed his fourth annual report. He states that the tuberculosis death-rate for the county of Aberdeen during 1919 was the lowest for six years, the number of cases notified being 342; 242 of these were pulmonary and 100 non-pulmonary or surgical tuberculosis. 248 were notified in the districts and 94 in the burghs—that is, 2·1 per 1000 in th former and 2·3 per 1000 in the latter case. Of the case notified, 180 were males and 162 females. During the yea in the county of Aberdeen 50 soldiers and sailors receive treatment in institutions, 78 were treated either at thei homes or at the dispensary, and 12 had the use of shelters The sources of notification were: from general practitioners 267; from military and naval medical officers, 45; from medical officers of medical and surgical hospitals, 9; from medical officers of health of other areas ("transfers"), 8 from medical officers of asylums, 8; from school medica officers, 3; from tuberculosis medical officers, 2. The repor again calls attention to the large number of "box-beds" still in existence, although they are less common than they formerly were, and also to the surprising number of tuberculous persons who, without the knowledge of their doctor, try and use quack medicines, paying perhaps 24*s.* for a bottle the contents of which would probably only cost 9*d.* It is the poorer class of patient who purchase those supposed remedies, and in many cases they stint themselves of the necessaries of life in order to secure a phantom cure. Dr. Rae urges that the composition of those quack remedies should be exposed, and, if possible, their sale prohibited.

THE University of Alberta is preparing to make extensive additions to its buildings and amenities according to a local correspondent An estimate of requisitions has been made amounting to $750,000 to be employed in furnishing more class room and laboratory accommodation which is urgently needed Although the University is a comparatively new one, the registration of medical students for the present term has reached 180, of whom 72 constitute the freshman class

MEDICAL GOLF CHAMPIONSHIP —The 1920 Medical Golfing Society Tournament will be held on Thursday, June 24th, at Northwood, Middlesex by kind permission of the Northwood Golf Club The *Medical Golf Championship Cup*, presented by THE LANCET in 1914, will be held by the player on the Medical Register who makes the best scratch return v Bogey, this competition is a regular feature at the annual meeting of the Medical Golfing Society Any one on the Medical or Dental Register can join the society by payment of the annual subscription (5s), which includes entrance to the tournament Full particulars of the tournament with form of entry, can be obtained from L Eliot Creasy, hon secretary and treasurer, 36 Weymouth street, London, W 1 (T 904, Paddington)

A ONE SEATER FOR THE DISABLED —A demonstration of motor cycles and other vehicles adapted for the use of disabled persons is to be held on June 12th in the Inner Circle, Regent's Park London, N W One of the designs is described as consisting of a side car body on four wheels driven by electricity and made in different varieties, controllable entirely by hand, entirely by foot, or by both to suit the special case It is said to be capable of running for 35 miles without re charging at a maximum speed of 15 miles per hour, while the cost of a full battery charge is only 2s If the price is not prohibitive this machine should prove popular among the disabled, as it is stated to be light in weight and simple to run

ULSTER MEDICAL SOCIETY —At the annual meeting of this society held on May 27th at the Medical Institute, Belfast, with Mr Andrew Fullerton the President, in the chair, a report was submitted showing that, beside the honorary Fellows, there was an increase in ordinary Fellows and Members the total Fellows being 123 and Members 87—210 in all Financially there was a deficit, and a special committee was appointed to look into the matter after various suggestions—such as efforts to get more doctors to join the society, an increase of subscription, or a decrease of expenditure—had been brought forward The following office bearers for session 1920–21 were elected —

President *Dr Thomas Houston* Ex President Mr Andrew Fullerton Vice Presidents Dr Samuel Agnew (Lurgan) and Dr J E MacIlwaine Honorary Treasurer Dr S I Turkington Honorary Secretary Dr W W D Thomson Honorary Librarian *Dr W L Storey Honorary Editorial Secretary Dr R Marshall* Council Dr C G Lowry Mr Howard Stevenson Dr S T Irwin Dr V G L Fielden Mr W Burns and Dr Boyd Campbell

INCREASE OF PROSTITUTION AND VENEREAL DISEASES IN VIENNA —Our Vienna correspondent writes An energetic but apparently futile fight is being organised against one of the chief menaces to public health—the increase of prostitution, as manifested by the results of the frequent raids of the police on certain hotels and inns The war caused in all large cities a severe relaxation of sexual morals, but nowhere in such a degree as in Vienna The general financial collapse tends to make things worse still as poverty is very often the cause of the first stumbling from the road of respectability, which soon is followed by a true downfall The subject was not considered a fit one for public discussion until a few years ago, but the great danger involved in the extension of venereal disease has necessitated its ventilation a hopeful battle cannot be fought without information and explanation to the masses The daily press brings alarming numbers and facts, which relate to all classes of the population Whilst formerly the chief sources of secret or open prostitutes were servant girls out of work, waitresses or factory girls, now a large percentage are recruited from clerks, typists daughters of respectable families or even wives of the poorly paid clerks or civil servants In 1919 over 7000 females, of whom 2700 were diseased were arrested for "illegal" prostitution 2400 were dealt with by a special department of the Board of Health 800 of these were between 18 and 21 years of age and 42 per cent were diseased 1392 were under 18 years old with 50 per cent infected In the first quarter of 1920 the same Board examined 800 cases with 40 per cent disease, 90 girls were between 14 and 18 years old with 60 per cent of disease These figures show that the increase of venereal disease is a real danger and cannot be dealt with except by up to-date measures It is futile to search for the infected girls in the inns and hostelries, and lock them up or bring them for compulsory treatment to hospitals whilst the men are left alone The necessity of coercive measures against men found infected on such occasions is becoming more and more appreciated The sanitary police service in Austria is demanding a new law by which it would have power to subject to effective medical treatment all persons found ill from sexual disease and behaving in a way that favours transmission of the illness Naturally such a law would mean severe restriction of individual liberty, but it appears to be the only policy to adopt The transmission of disease by infected men is at least as dangerous, and as likely, as by women and must be treated on the same principles as, for instance, cases of scarlet fever or diphtheria, which are at once made innocuous by separation and hospitalisation The new regulations will be issued shortly

MEDICAL MAGISTRATE —Mr Charles Edwards has been placed on the commission of the peace for the borough of Bridport (Dorset)

PRESENTATION TO A MEDICAL MAN.—Dr Arthur Napper, of Cranleigh Surrey, was last week presented with an armchair and a cheque for £750 on his retirement after 46 years of public life

FLORENCE NIGHTINGALE MEDAL —This medal was instituted by the International Red Cross Committee in 1912 in memory of the work of Miss Florence Nightingale, to be distributed annually to six trained nurses who in the opinion of the Committee, have rendered exceptional service in connexion with nursing During the war no distribution was made but shortly after the signing of Peace it was decided to award 50 of these medals and all National Red Cross Societies were requested to submit recommendations for consideration by the Committee Forty two medals have been awarded and amongst the recipients are included the following whose names were submitted by the British Red Cross Society —

Mrs John Lambert of the Royal Naval Nursing Reserve for services in 1915 and 1916 especially on the Hospital Ship *Reva* at Gallipoli

Miss Beatrice Isabel Jones R R C C B E Matron Q A I M N S for services in Mesopotamia since 1916

Miss Gladys Laura White (Sister) B R C S for service 1915 to 1918 especially at No 9 B R C S Hospital at St Omer (No 36 Casualty Clearing Station)

Miss Kate Maxey R R C M M Sister T F Nursing Service for services from 1914 to 1918 especially at No 58 Casualty Clearing Station

Miss Gertrude Mary Wilton Smith Q A I M N S for services as Sister in Charge of Anglo-French Hospital Train No 7 and No 3 Casualty Clearing Station France

Miss Margaret Clotilde Macdonald R R C Matron in Chief of the Canadian Army Nursing Service

Miss Lucy Minchin Nursing Sister of the British Army in India and Mesopotamia

Miss Hester Maclean R R C Matron in Chief New Zealand Army Nursing Service

Mrs F R Creagh O B E R R C Matron in-Chief South African Military Nursing Service

THE LATE DR R EDWARDS —The death has occurred at Carlisle of Dr Robert Edwards following influenza and pneumonia Dr Edwards graduated at Edinburgh University in 1907, and his first appointment was that of house surgeon at the Cumberland Infirmary at Carlisle Here he remained a year and then became successively a house surgeon at the Great Ormond street Hospital for Sick Children London and a resident surgeon at the Royal Sea Bathing Hospital at Margate Seven or eight years ago he began to practise at Carlisle, where he soon became popular Soon after the war began he became acting assistant surgeon at the Cumberland Infirmary where he had previously been placed in charge of the X ray and electrical departments He then joined the army and went abroad but was sent back to England owing to ill health and for some time served under Sir Robert Jones at the Orthopaedic Hospital at Liverpool When later he returned to Carlisle he was appointed surgeon with the rank of major at the Fusehill Military Hospital and gradually resumed his private practice Dr Edwards had attained considerable skill as a surgeon and was specially noted for his abdominal work During and since the war he had specialised more particularly in orthopaedic surgery At the Gretna railway disaster in 1915 Dr Edwards rendered invaluable service repeatedly inserting himself under burning coaches to liberate and attend to the injured in spite of cries of warning from the railway officials who expected a gas explosion any minute In order to release two soldiers pinned beneath a coach and in danger of being burnt alive he amputated both legs of one man and one leg of the other He thus saved the life of one of them the other dying from shock When Dr Edwards himself arrived at the Cumberland Infirmary his coat had been burnt off his back The news of his death at the early age of 35 has been received with great regret and much sympathy is felt with the widow and two young children who survive him

A recent flag day held by the League of the Roses, Miss M. F. Roby chairman, realised £326 18*s.* 5*d.* for the Great Northern Central Hospital.

Sir Robert Borden, the Prime Minister of the Canadian Parliament, has written to Mr. Rockefeller expressing the appreciation of the Canadian people for his gift of $5,000,000 to Canadian medical education.

The first annual conference of the subassistant surgeons of Madras Presidency was held recently at the Madras Medical College, Major-General Giffard, Surgeon-General with the Madras Government, presiding. About 200 subassistant surgeons from the city attended.

Dr. John O'Conor, senior medical officer of the British Hospital, Buenos Ayres, has been appointed a Knight Commander of the Most Excellent Order of the British Empire for services in connexion with the war.

Indian Medical Service Dinner.—The annual dinner of the Indian Medical Service will be held at the Trocadero on Tuesday, June 8th, at 7.45 P.M., Major-General G. F. A. Harris, C.S.I., in the chair. Tickets and all particulars may be obtained from the joint honorary secretary, Colonel J. J. Pratt, I.M.S. (retired), 63, Addison-road, London, W. 14.

The Board of Governors of the American Hospital in London are giving a dinner at Claridge's Hotel on July 6th, at which the guest of the evening will be Dr. Charles W. Mayo, of Rochester, U.S.A. The American Ambassador, Lord Bryce, and Lord Reading are associated with the hosts of the dinner, and Mr. Philip Franklin, 27, Wimpole-street, W., is acting as honorary secretary.

Dr. Addison has appointed Mr. Llewelyn Williams, M.C., to be Medical Member of the Welsh Board of Health with the status of a Senior Medical Officer of the Ministry of Health. Dr. Meredith Richards, who has been acting temporarily as medical member of the Welsh Board of Health, has been appointed to the headquarters establishment of the Ministry of Health.

Imperial War Museum and Great Victory Exhibition.—The opening ceremony of the above exhibition will be held at the Crystal Palace on Wednesday, June 9th, at 11.15 A.M., when the King will preside. We learn that the war exhibits are of a most interesting and varied character, and should occupy the visitor's attention for some time. Medical men will be attracted, amongst other sections, to the Naval Medical Section, organised by Surgeon-Commander M. H. Knapp, R.N. Altogether the exhibition promises to be a great national event.

A List of Special Schools.—The Board of Education has just issued a list of special schools for blind, deaf, and defective children in England and Wales, with a note as to the amount of accommodation and average attendance. As this list is intended solely for official use the schools are entered under the county in which they are situated without an indication of the authority responsible for them. It appears that in England 39 day and 19 residential schools are provided for the blind, 29 day and 20 residential for the deaf, 171 day and 20 residential for the mentally defective. Schools for tuberculous and non-tuberculous children are classified together. It is interesting to note that London contains more than one-third of the day schools for blind, deaf, and physically defective children.

A Holiday Course in Tuberculosis.—A holiday course, under the auspices of the Assistance Publique of Paris, will be held from July 19th to 31st, each day at 2 P.M., at the Maritime Hospital at Berck-sur-Mer (Pas-de-Calais). It will consist of 12 lessons on osteo-articular and ganglionic tuberculosis and some elements of practical orthopædics by the following medical men: M. Menard, honorary chief surgeon of the Maritime Hospital; M. Sorrel, chief surgeon; MM. Andrieu and Tridon, assistant surgeons; M. Mozer, chief of the hospital laboratory; M. Parin, chief of the laboratory of radiology of the hospital. The course will comprise the elements of diagnosis furnished by the laboratory and radiology, Pott's disease, coxalgia, tuberculosis of the knee and tarsus, tuberculosis of the shoulder, elbow, and wrist, tuberculous osteitis, non-tuberculous osteitis and chronic osteo-arthritis with their clinical and laboratory diagnoses, chronic adenitis, helio-marine, radiotherapeutic and surgical treatment, rickets and its treatment, deformities and osteo-articular troubles of adolescence, scoliosis and its treatment. The mornings will be devoted to practical demonstrations as follow: Clinical examinations on Mondays, operations and punctures on Tuesdays and Fridays, plasters Wednesdays and Saturdays, laboratory demonstrations Thursdays. The fee for the course is 150 francs (Internes of the Paris hospitals are exempt). Enrolment should be made by letter addressed to Dr. Parin, Hôpital Maritime, Berck-Plage (Pas-de-Calais), France.

East Sussex Hospital.—The governors of the East Sussex Hospital at Hastings have elected Dr. H. Stanley, Mr. J. W. M. King, and Mr. H. Groome as the first honorary life governors in recognition of valuable work in the interests of the institution.

Royal Devon and Exeter Hospital.—As a result of the appeal for £20,000 for the extension of the Royal Devon and Exeter Hospital the sum of £12,622 has been received, and it is hoped that the remaining amount will be shortly subscribed.

Devon and Cornwall Ear and Throat Hospital, Plymouth.—At the annual meeting of the subscribers to this institution held on May 28th it was reported 1014 patients had been treated compared with 760 in 1918. The financial statement showed a deficit of £100. The chairman, the mayor, alluded with regret to the retirement of Mr. C. E. Bean, who had been honorary surgeon to the hospital since its foundation 33 years ago, and paid a tribute to the value of his services.

The late Mr. W. Eager.—Wilson Eager, L.R.C.P., M.R.C.S., L.S.A., died at his residence, Woodbridge, Suffolk, in his seventy-sixth year. The deceased was a son of the late Mr. R. Eager, a surgeon, of Guildford. He was for 27 years medical superintendent of the Suffolk County Asylum, Melton, now known as St. Audry's Mental Hospital. He resigned in 1897, and joined his elder brother at Northwoods Private Asylum, near Bristol; ten years later he retired from active work, and went to live at Woodbridge, Suffolk, where he was highly esteemed. His son, Dr. Richard Eager, is deputy medical superintendent of the Devon Mental Hospital.

British Waterworks Association.—The ninth annual general meeting of this association will be held in the Council Chamber, The Exchange, Nottingham, on Thursday, July 1st. The proceedings include the reading and discussion of interesting papers on water undertakings from both the economic and hygienic point of view, and the members of the association and their friends are invited to visit the filtration plant and pumping stations belonging to the Nottingham corporation. The sources of water-supply in Nottingham are manifold, including the moorland area of the Derwent Valley, the deep wells in sandstone at Bestwood and Boughton, and the artesian boreholes at Burton Joyce. The meeting altogether promises very interesting proceedings.

Maternity Home for Sailors' Wives.—The Central Commtitee of the Navy League has given £30,000 for the establishment of maternity homes for the wives of sailors and Marines at each of the three principal naval ports—Portsmouth, Devonport, and Chatham—£10,000 for each port. In 1917 the women of Canada collected a handsome sum as an expression of their admiration for the British Navy. Of that money £3000 were handed over to the Commander-in-Chief at Portsmouth for maternity purposes. A meeting to inaugurate a scheme for its application was held in the Town Hall, Portsmouth on May 26th, when it was stated that a suitable house in Southsea had been purchased for £4000 and was being equipped as a maternity home. The plans have now received the official approval of the Ministry of Health. The institution of the home has the support of all ranks and ratings in the navy.

Tuberculosis in Aberdeenshire.—Dr. H. J. Rae, the tuberculosis officer for the county of Aberdeen, has completed his fourth annual report. He states that the tuberculosis death-rate for the county of Aberdeen during 1919 was the lowest for six years, the number of cases notified being 342; 242 of these were pulmonary and 100 non-pulmonary or surgical tuberculosis. 248 were notified in the districts and 94 in the burghs—that is, 2·1 per 1000 in the former and 2·3 per 1000 in the latter case. Of the cases notified, 180 were males and 162 females. During the year in the county of Aberdeen 50 soldiers and sailors received treatment in institutions, 78 were treated either at their homes or at the dispensary, and 12 had the use of shelters. The sources of notification were: from general practitioners, 267; from military and naval medical officers, 45; from medical officers of medical and surgical hospitals, 9; from medical officers of health of other areas ("transfers"), 8; from medical officers of asylums, 8; from school medical officers, 3; from tuberculosis medical officers, 2. The report again calls attention to the large number of "box-beds" still in existence, although they are less common than they formerly were, and also to the surprising number of tuberculous persons who, without the knowledge of their doctor, try and use quack medicines, paying perhaps 24*s.* for a bottle the contents of which would probably only cost 9*d.* It is the poorer class of patient who purchase those supposed remedies, and in many cases they stint themselves of the necessaries of life in order to secure a phantom cure. Dr. Rae urges that the composition of those quack remedies should be exposed, and, if possible, their sale prohibited.

THE University of Alberta is preparing to make extensive additions to its buildings and amenities, according to a local correspondent An estimate of requisitions has been made amounting to $750,000, to be employed in furnishing more class room and laboratory accommodation, which is urgently needed Although the University is a comparatively new one, the registration of medical students for the present term has reached 180, of whom 72 constitute the freshman class

MEDICAL GOLF CHAMPIONSHIP —The 1920 Medical Golfing Society Tournament will be held on Thursday, June 24th, at Northwood, Middlesex, by kind permission of the Northwood Golf Club The Medical Golf Championship Cup, presented by THE LANCET in 1914, will be held by the player on the Medical Register who makes the best scratch return v Bogey, this competition is a regular feature at the annual meeting of the Medical Golfing Society Anyone on the Medical or Dental Register can join the society by payment of the annual subscription (5s), which includes entrance to the tournament Full particulars of the *tournament, with form of entry*, can be obtained from L Eliot Creasy, hon secretary and treasurer, 36, Weymouth street, London, W.1 (T 904, Paddington)

A ONE-SEATER FOR THE DISABLED —A demonstration of motor cycles and other vehicles adapted for the use of disabled persons is to be held on June 12th in the Inner Circle, Regent's Park, London, N W One of the designs is described as consisting of a side car body on four wheels, driven by electricity and made in different varieties, controllable entirely by hand, entirely by foot, or by both, to suit the special case It is said to be capable of running for 35 miles without recharging at a maximum speed of 15 miles per hour, while the cost of a full battery charge *is only 2s If the price is not prohibitive this machine* should prove popular among the disabled, as it is stated to be light in weight and simple to run

ULSTER MEDICAL SOCIETY.—At the annual meeting of this society, held on May 27th at the Medical Institute, Belfast, with Mr Andrew Fullerton, the President, in the chair, a report was submitted showing that, beside the honorary Fellows, there was an increase in ordinary Fellows and Members, the total Fellows being 123 and Members 87—210 in all Financially there was a deficit, and a special *committee was appointed to look into the matter after* various suggestions—such as efforts to get more doctors to join the society, an increase of subscription, or a decrease of expenditure—had been brought forward The following office bearers for session 1920-21 were elected —

President Dr Thomas Houston Ex President Mr Andrew Fullerton Vice-Presidents Dr Samuel Agnew (Lurgan) and Dr J E MacIlwaine Honorary Treasurer Dr S I Turkington Honorary Secretary Dr W W D Thomson Honorary Librarian, Dr W L Storey Honorary Editorial Secretary Dr R Marshall Council *Dr C G Lowry Mr Howard Stevenson, Dr S T Irwin,* Dr V G L Fielden Mr W Burns and Dr Boyd Campbell

INCREASE OF PROSTITUTION AND VENEREAL DISEASES IN VIENNA —Our Vienna correspondent writes An energetic but apparently futile fight is being organised against one of the chief menaces to public health—the increase of prostitution, as manifested by the results of the *frequent raids of the police on certain hotels* and inns The war caused in all large cities a severe relaxation of sexual morals, but nowhere in such a degree as in Vienna The general financial collapse tends to make things worse still, as poverty is very often the cause of the first stumbling from the road of respectability, which soon is followed by a true downfall The subject was not considered a fit one for public discussion until a few years ago, but *the great danger involved in the extension of* venereal disease has necessitated its ventilation, a hopeful battle cannot be fought without information and explanation to the masses The daily press brings *alarming* numbers and facts, which relate to all classes of the population Whilst formerly the chief sources of secret or open prostitutes were servant girls out of work, waitresses, or factory girls, now a large percentage are recruited from clerks, typists, *daughters of* respectable families, or even wives of the poorly paid clerks or civil servants In 1919 over 7000 females, of whom 2700 were diseased were arrested for "illegal" prostitution 2400 were dealt with by a special department of the Board of Health, 800 of these were between 18 and 21 years of age, and 42 per cent were diseased 1392 were under 18 years old, with 50 per cent infected In the first quarter of 1920 the same Board examined 800 cases with 40 per cent disease, 90 girls were between 14 and 18 years old, with 60 per cent of disease These figures show that the increase of venereal disease is a real danger and cannot be dealt with except by up to date measures It is futile to search for the infected girls in the inns and hostelries, and lock them up or bring them for compulsory treatment to hospitals, whilst the men are left alone The necessity of coercive measures against men found infected *on such occasions* is becoming more and more appreciated The sanitary police service in Austria is demanding a new law, by which it would have power to subject to effective medical treatment all persons found ill from sexual disease and behaving in a way that favours transmission of the illness Naturally such a law would mean severe restriction of individual liberty, but it appears to be the only policy to adopt The transmission of disease by infected men is at least as dangerous, and as *likely, as* by women, and must be treated on the same principles as, for instance, cases of scarlet fever or diphtheria, which are at once made innocuous by separation and hospitalisation The new regulations will be issued shortly

MEDICAL MAGISTRATE —Mr. Charles Edwards has been placed on the commission of the peace for the borough of Bridport (Dorset)

PRESENTATION TO A MEDICAL MAN.—Dr. Arthur Napper, of Cranleigh, Surrey, was last week presented with an *armchair and a cheque for £750 on* his retirement after 46 years of public life

FLORENCE NIGHTINGALE MEDAL —This medal was instituted by the International Red Cross Committee in 1912 in memory of the work of Miss Florence Nightingale, to be distributed annually to six trained nurses who, in the opinion of the Committee, have rendered exceptional service in connexion with nursing During the war no distribution was made, but shortly after the signing of Peace it was decided to award 50 of these medals, and all National Red Cross Societies were requested to *submit recommendations* for consideration by the Committee Forty two medals have been awarded and amongst the recipients are included the *following, whose names were submitted* by the British Red Cross Society —

Mrs John Lambert of the Royal Naval Nursing Reserve, for services in 1915 and 1916 especially on the Hospital Ship *Rewa* at Gallipoli

Miss Beatrice Isabel Jones R R C C B E, Matron Q A I M N S for services in Mesopotamia since 1916

Miss Gladys Laura White (Sister) B R C S, for service 1915 to 1918 especially at No 9 B R C S Hospital at St Omer (No 36 Casualty Clearing Station)

Miss Kate Maxey, R R C, M M, Sister T F Nursing Service for services from 1914 to 1918, especially at No 58 Casualty Clearing Station

Miss Gertrude Mary Wilton Smith, Q A I M N S, for services as Sister in Charge of Anglo-French Hospital Train No 7 and No 3 Casualty Clearing Station France

Miss Margaret Clotilde Macdonald R R C Matron in Chief of the Canadian Army Nursing Service

Miss Lucy Minchin, Nursing Sister of the British Army in India and Mesopotamia

Miss Hester Maclean, R R C Matron in Chief New Zealand Army Nursing Service

Mrs E R Creagh, O B E, R R C Matron in Chief South African Military Nursing Service

THE LATE DR. R. EDWARDS —The death has occurred at Carlisle of Dr Robert Edwards, *following* influenza and pneumonia Dr Edwards graduated at Edinburgh University in 1907, and his first appointment was that of house surgeon at the Cumberland Infirmary at Carlisle Here he remained a year, and then became successively a house surgeon at the Great Ormond street Hospital for Sick Children, London, and a resident surgeon at the Royal Sea Bathing Hospital at Margate Seven or eight years ago he began to practise at Carlisle, where he soon *became popular* Soon after the war began he became acting assistant surgeon at the *Cumberland Infirmary, where he had previously been placed in charge of the X ray and electrical departments* He then joined the army and went abroad, but was sent back to England owing to ill health, and for some time served under Sir Robert Jones at the Orthopædic Hospital at Liverpool When later he returned to Carlisle he was appointed surgeon, with the rank of major, at the Fusehill Military Hospital, and gradually resumed his private practice Dr Edwards had attained considerable skill as a surgeon, and was specially *noted for his abdominal work During* and since the war he had specialised more particularly in orthopædic surgery At the Gretna railway disaster in 1915 Dr Edwards rendered invaluable service, repeatedly inserting *himself under* burning coaches to liberate and attend to the injured, in spite of cries of warning from the railway officials, who expected a gas explosion any minute In order to release two soldiers pinned beneath a coach and in danger of being *burnt alive he amputated* both legs of one man and one leg of the other He thus saved the life of one of them, the other dying from shock When Dr Edwards himself arrived at the Cumberland *Infirmary* his coat had been burnt off his back The news of his death at the early age of 35 has been received with great regret, and much sympathy is felt with the widow and two young children who survive him

The Services.

THE HONOURS LIST.

THE following appointments to the Most Excellent Order of the British Empire, for services in connexion with the war, are announced:—

K.B.E.—Dr. John O'Conor, Head of the British Hospital in Buenos Ayres.

O.B.E.—Mrs. Constance Muriel Astley Meyer, Civil Surgeon, attached R.A.M.C.

M.B.E.—Dr. Herman Arthur Macdonald, Medical Officer, Alverstoke Auxiliary Hospital, Hampshire.

ROYAL ARMY MEDICAL CORPS.

Major E. V. Aylen relinquishes the temporary rank of Lieutenant-Colonel.

Temp. Major J. J. Abraham relinquishes the acting rank of Lieutenant-Colonel.

Temp. Capt. A. Brown to be acting Lieutenant-Colonel.

Capt. A. S. Cane to be temporary Major whilst specially employed.

The undermentioned relinquish the acting rank of Major: Capts. A. T. J. McCreery (Bt. Major), C. D. K. Seaver, H. G. Trayer, Temp. Capts. H. B. Graham, W. T. Currie, A. G. Gilchrist, R. Massie, A. C. S. Courts, J. H. Peek.

Capt. T. J. Hallinan is seconded for service under the Civil Administration of Mesopotamia.

Lieutenants (temporary Captains) to be Captains: W. M. Cameron, A. G. Harsant, M. StC. Hamilton, A. Rodd.

J. S. F. J. Kerr to be temporary Lieutenant.

Officers relinquishing their commissions:—

Captains granted the rank of Lieutenant-Colonel: C. J. A. Griffin, C. N. Gover, D. C. Barron, E. M. Cowell, G. T. van der Vijver, T. Y. Barkley, A. T. Pitts.

Captains, granted the rank of Major: F. Cook, C. E. H. Gater, G. Dalziel, J. Purdie, A. Glen, W. Barclay, W. C. B. Meyer, O. H. Mavor, M. W. Paterson, C. J. B. Way, B. Goldsmith, C. Nicholson, S. Wickenden, C. Lovell, A. B. Mitchell, J. R. McCurdie, R. L. Newell, K. K. Drury, D. Dougal, A. J. Gilchrist, T. F. Corkhill, V. Wiley, E. Watson-Williams, W. J. Adie, W. Johnson, M. J. B. F. Burke-Kennedy, G. G. Marshall, G. Marshall, J. B. Scott, E. R. Lovell, W. R. Blore, A. L. Shearwood, G. R. Bruce, J. H. Beverland, D. S. Badenoch, A. Wilson, H. R. Friedlander, G. G. Alderson, J. C. Spence, J. Paulley, R. P. Ballard, K. W. Lewis, W. McCombie, W. B. Cathcart, H. G. Crawford, W. B. Postlethwaite, R. P. A. Kirkland, E. C. W. Starling, G. T. Mullally, (Bt. Maj.) R. C. Ozanne, P. J. Gaffikin, A. A. Smalley, T. G. Fleming, J. Swan, E. J. Bradley, W. Murdock, W. B. Foley, J. B. Cavenagh, E. A. Mills, D. G. Stoute, F. Gamm, D. Colombos, A. R. Hill, J. B. Hanna, H. W. H. Holmes, J. A. Stewart, D. McIntyre.

Captains retaining the rank of Captain: C. G. Schurr, H. E. Creswell, H. K. V. Soltau, R. P. S. Mason, W. C. Mackie W. Broughton-Alcock, J. W. McNee, H. E. B. White, J. S. Dockrill, J. L. Perceval, E. S. Mawe, C. McL. West, D. J. Steele, S. D. Lodge, J. J. D. La Touche, F. H. Goss, G. S. Trower, G. C. L. Woodroffe, J. L. Kilbride, J. C. Young, S. K. Young, R. C. B. Ramsay, J. A. W. Cullen, F. L. P. G. Bennett, J. H. Owen, M. J. Graham, F. A. Belam, J. J. B. Edmond, D. M. M. Fraser, D. C. L. Vey, A. Smith, E. A. Dyson, H. A. Fawcett, S. W. Rintoul, H. B. Goulding, A. McM. Paterson, N. A. Martin, F. G. Lescher, E. K. Ryan, H. M. Pope, W. T. Quinlan, H. W. Evans, H. S. Pemberton, J. Le M. Kneebone, J. K. R. Landells, R. O. Eades, W. S. Birch, A. E. H. Reid, A. J. Ewing, R. N. O. Moynan, J. V. L. Grant, T. M. Miller, M. Avent, B. Greillier, C. H. Attenborough, H. J. S. Morton, E. S. Walls, J. P. Mitchell, J. P. Davies, S. W. M. Jones, G. N. Smyth, R. S. Woods, F. A. Bearn, J. W. Craw, G. W. Wood, J. P. Stallard, T. F. Hegarty, B. Murphy, P. W. Ransom, W. S. Haydock, F. R. Kerr, C. Jacobs, G. A. Hodgson, P. Thornton, J. E. Allan, J. Cowan, G. L. Jones, F. Sykes, L. H. W. Williams, W. H, Shephard, F. V. Bevan-Brown, O. D. Child, H. Smith, J. A. Ryle, C. F. Hacker, J. K. J. Haworth, L. H. W. Iredale, G. M. Roberts, J. S. Robinson, G. D. Read, W. A. MacLennan, G. H. C. Mold, J. F. Hill, G. C. Dixon, J. N. McIntosh, G. F. Clifton, E. F. Guy, J. McKerchar, W. A. Elliott, T. B. Heaton, F. H. Kennedy, T. G. Shand, C. Grant, L. A. Lewis, J. S. Pooley, J. Kennedy, C. A. Mason, W. B. Wood, M. McKnight, A. L. Anthony, C. Gamble, H. L. Garson, W. K. Russell, J. H. Stewart, C. C. Waddington, G. W. Watson, W. A. Young, W. W. Phillips, W. M. Dickson, L. B. C. Marksman, T. Sheedy, J. L. McBean, F. M. Barnes, J. G. Bennett, T. P. Inglis, F. C. Lapage, H. M. Williams, F. A. Duffield, F. Sanders, J. W. Wood, G. M. Scott, J. O. Reid, S. W. Lund, P. B. Corbett, J. Lawson, N. B. Graham, R. O. C. Thomson, D. W. J. Andrews, J. G. Hendry, J. S. Armstrong, S. Brown, A. R. Laurie, H. T. Chatfield, A. L. C. Mackenzie, W. W. Blair, T. R. Davies, I. F. Mackenzie, K. P. Brown, H. D. Wright, G. Morris, G. Irving, D. R. Jones, J. N. L. Blamey, C. P. L. Carrier, A. McL. Ferrie, M. Foster, W. N. Greer, I. MacKenzie, J. Milne, C. P. Pemberthy, B. J. Ryrie, J. M. Smellie, W. L. Ingham, C. Rudd, E. W. Fish, H. C. Broadbridge, W. J. Vance, C. W. Dudley, G. S. Davidson, M. Dwyer, G. Lapage, E. B. Alabaster, R. Colley, A. C. Brown, J. W. Dalglish, J. F. Duthie, E. G. S. Hall, A. F. McMillan, R. Rodger, J. B. Steven, R. W. MacDonald, J. A. Buchanan, J. H. Albinson, D. D. Evans, H. S. Moore, R. B. Stewart, R. J. Staley, D. F. Standing, A. H. Craig, G. Ewen, G. J. Key, A. C. MacDonald, A. G. P. Wills, W. O. F. Sinclair, H. J. Wright, G. E. Kidman, J. J. Murphy, E. H. V. Hensley, A. R. Steven, W. A. Malone, A. Johnstone, G. S. Mather, J. Ross, F. B. Macaskie, P. R. E. Kirby, A. C. Dickey, J. P. Bracken, W. Saunderson, T. Wilson, J. D. Dyson, C. E. Bond, J. A. Murray, E. Lipman, D. H. Anthony, J. E. Kitchen, J. B. Hume, W. E. Wilson, T. Crisp, W. Richards, G. K. E. Inman, J. E. Bannen, J. Beveridge, H. D. Brown, W. Donald, T. J. Honeyman, J. MacA. Mackintosh, D. B. Robertson, H. Chadwick, J. Stirling, H. W. Torrance, A. G. Anderson, F. J. C. Johnstone, J. Ratcliffe, J. Sellar, N. N. B. Fleming, R. B. Hawes, C. E. Hopwood, J. R. Banks, J. A. Hill, J. H. Vance, E. Butler, W. Agar, C. Y. Roberts, E. M. L. Morgan, T. P. Williams, P. R. Riggall, G. S. Martin, F. N. Sidebotham, A. R. Balmain, R. F. Jarrett, J. W. G. Steell, R. G. Simpson, T. B. Bailey, L. Cunningham, R. Moser, B. H. Simon, G. S. Lawrence, J. F. C. Braine, G. W. Heckels, E. Newton, S. C. Swinburne, G. S. Wilson, W. Yeoman, G. G. Jack, W. M. Morris, W. B. Lawson, D. Mitchell, H. C. Roberts, F. K. Hayman, G. E. Archer, J. H. E. Annequin, W. C. Craig, G. C. McEwan, R. A. Woodhouse, N. C. L. B. Tweedie, N. S. Tirard, H. Franklin, C. J. Penny, R. W. Lush, L. S. Gathergood, T. L. Heath, F. C. A. Frith, H. D. McIlroy, S. A. T. Ware, A. T. Woodward, E. R. Longstaff, M. C. Joynt, G. A. Harrison, R. Woodside, D. C. Bluett, A. R. Dingley, P. A. Buxton, J. W. Gordon, J. A. Tolmie, A. A. Fitch, J. B. Mudge, H. A. G. Dykes, W. F. Mason, W. G. Verniquet, A. H. Mitchell, F. R. Leblanc, E. A. C. Langton, W. Christopher, R. L. Jones, A. G. Lumsden, V. T. B. Yule, R. Nixon, P. B. Pinkerton, E. Bramley, J. D. Johnson, R. R. Garden, J. Allison, J. L. Hill, J. M. Martin, H. Patlansky, R. B. Smith, W. McElroy, F. W. Hebblethwaite, H. F. Hollis, W. H. Kerr, A. D. C. McGowan, D. W. M. MacKenzie, J. W. Patterson, H. B. Sergeant, F. J. Jack, D. Lennox, S. N. Dykes, A. J. B. Griffin, E. S. Stubbs, H. W. Leatham, C. C. Chesterman, F. O. Taylor, H. W. Featherstone, J. E. Carpenter, P. A. Ashcroft, E. B. Andreae, A. L. Packham, S. Vidot, A. G. E. Wilcock, T. C. Murphy, J. M. Norman, E. W. Bowell, H. J. C. Churchill, W. W. Newton, W. Brown, L. W. Hughes, A. B. Black, R. G. Battersby, J. J. Mulvey, N. S. Bruce, R. McGregor, W. J. Walters, A. Rose-Innes, A. Robertson, L. Jefferson, J. Rowland, J. H. Wiseman, W. H. White, R. N. Burton, L. Gill, H. Gainsborough, W. R. Mathewson, S. T. Alexander, J. C. C. Howe, J. Wilson, J. A. Keen, A. B. MacDougall, W. L. Agnew, C. G. Irwin, J. Irvine, H. E. Charles, H. V. Horsfall, J. H. Parker, N. Pick, C. H. Smith, C. Reid, W. Eidinow, A. B. Platt, W. T. G. Boul, R. D. Aylward, H. M. Holt, N. Kletz, W. W. Brown, R. Mailer, J. H. R. Smith, S. L. Smith, W. A. Weatherhead, R. J. L. Fraser, E. P. Irving, J. Joels, D. S. Mitchell, F. W. Sandeman, H. D. Apergis, A. Y. Milne, H. G. Morris-Jones, H. B. Dodwell, M. Edwards, N. P. R. Galloway, J. G. Allan, F. Bendix, C. M. Titterton, H. B. Renton, F. Jones, A. McL. Pickup, O. C. Carter, G. L. Malcolm-Smith, W. U. D. Longford, J. J. Robertson, A. B. Cocker, J. Michaelson, J. Marshall, J. W. Morris, M. J. Hilton, J. G. McK. Macaulay, G. R. Sharp, E. S. Phillips, W. D. MacKinnon, R. F. C. H. Buchanan, J. B. D. Galbraith, A. Riddell, W. H. Wallace, H. Taylor, C. H. Warner, C. G. Magee, S. M. Riddick, W. B. Buer, J. Thompson, W. H. Rowden, J. L. D. Buxton, F. L. Richard, G. N. Groves, S. Riddiough, I. Liberman, W. M. Kerr, J. F. Twort, W. A. Fraser, W. G. F. Owen-Morris, J. W. C. Fairweather, C. F. J. Carruthers, W. P. Nelson, E. B. Ash, W. E. Le G. Clark, G. W. Coombes, T. Davies, D. V. Halstead, C. F. Rainer, R. B. Britton, B. B. Sharp, D. J. A. Lewis, J. Hope, A. V. Pegge, F. W. M. Lamb, R. M. Humphreys, A. E. Clark-Kennedy, C. B. Cohen, P. F. Bishop, R. B. Green, H. S. Carter, W. N. Goldschmidt, J. H. Tighe, M. Chalmers, A. E. Cochrane, W. S. L. McLeish, J. Nicolson, J. J. Treanor, W. A. Walker, N. E. ff. Kemm, J. Gilmour, J. C. Morris, J. S. Mann, C. W. Haward, W. A. Jackman, W. M. Savery, E. S. Jones, H. P. Gabb, R. W. C. Ball, T. A. Butcher, E. B. Verney, E. S. Rose, E. F. Rabey, E. Miller, G. S. L. Kemp, J. Peter, P. W. Putnam, R. H. Sutherland, D. O. Macdonald, H. A. Hill, M. Jackson, J. C. McGregor, A. C. Paterson, J. N. Gale, G. R. Ross, W. S. Herman, A. Abelson, J. Morrison, R. B. MacGregor, J. B. Potter, N. B. Peacock, E. S. Gawne, H. A. Cochrane, W. A. Coutts, E. M. E. Cumming, D. MacColl, R. J. Peters, J. H. E. Moore, W. A. Jaques, L. J. Schwartz, M. Melvin, J. Lipsey, T. McS. Wilson, C. O. Anderson, S. C. Critchley, C. P. Hines, A. Eidinow, E. E. R. Spurway, G. F. Peters, W. H. Simmons, F. Lyth, G. S. Lewis, L. H. Bartram.

Lieutenants retaining the rank of Lieutenant: G. V. Davies, F. Walton, J. W. Jones, G. V. W. Anderson, H. A. Chodah, A. R. C. McKerrow, W. A. Flynn, E. A. Leak, G. S. Escoffery, G. W. C. Dunlop, R. J. Patchett, W. A. Hewitson, J. M. Macpherson, S. G. Evans, E. A. Clegg, G. R. Baxter, C. C. H. Cuff, J. M. Melvin, D. Maclean, B. W. F. Armitage, G. G. Havers, M. S. Thomson, S. V. Goldhurst, A. S. Strachan, J. P. Kilty, A. P. McLeod, W. H. Palmer, W. A. Freedman, R. Gainsborough, A. St. G. J. McC. Huggett, W. B. Watson.

Temp. Major F. R. Lucas, T.D. (Major, 9th R. Scots, T.F.), relinquishes his temporary commission.

Temp. Lieut.-Col. A. D. Reid relinquishes his temporary commission.

Temp. Major W. T. F. Davies retains the rank of Major.

Temporary Captains granted the rank of Major: A. R. Green, H. H. Elliot, B. H. Woodyat.

Parliamentary Intelligence.

HOUSE OF COMMONS

TUESDAY, JUNE 1ST

Hospital Treatment of Soldiers

Mr CLOUGH asked the Secretary for War how many sick or invalid soldiers who would otherwise by this time have been demobilised were still being retained for hospital treatment at the expense of the State, whether such hospital treatment was now thoroughly adequate, and what was the cost of it as represented in the Estimates for this year — Sir A WILLIAMSON (Financial Secretary to the War Office) replied There are approximately 5000 soldiers in hospital in the United Kingdom who are eligible for demobilisation, and the daily cost is approximately £2500 The answer to the second part of the question is in the affirmative

Three and a Half Million War Pensions

Lieutenant Colonel ASSHETON POWNALL asked the Minister of Pensions whether he could state the number of those receiving pensions arising out of the war in this country and in France, and the number of persons engaged in this country on the administration of such pensions, and the corresponding figure for France —Mr MACPHERSON The number of persons receiving pensions in the United Kingdom in respect of disability or death in the present war is approximately 1,700 000, and, in addition, nearly 1 800 000 wives children, and other persons dependent on pensioners are receiving allowances—thus making the total number of beneficiaries approximately 3 500 000 The precise number of persons receiving similar pensions or allowances in France is not available, but I am informed that the number is in excess of 3 000 000 The number of persons engaged on the administration of pensions in the employ of the Ministry on May 1st was 24 892 It has not been found practicable to ascertain the corresponding figure for France

Major GODFREY PALMER asked the Minister of Pensions what was the present annual cost of war pensions, and whether he could now inform the House of the result of any actuarial or other estimate which had been prepared showing the anticipated increase or decrease of the annual cost of war pensions during the next 30 years —Mr MACPHERSON replied The cost of war pensions administered by the Ministry of Pensions for the financial year 1920-1921 is estimated at £118,211,000 This figure includes the cost of treatment, but excludes administrative expenses I am not aware of any attempt to forecast the future trend of the Pension Bill referred to, and having regard to the provision in the warrants for readjustment of rates in 1923 and annually thereafter according to the cost of living, I very *much doubt* whether any reliable figures could be obtained under present conditions

Site of London University

Sir WILLIAM DAVISON asked the President of the Board of Education what price the Government proposed to pay the Duke of Bedford for the site behind the British Museum which had been offered to the University of London, how many private residences, boarding houses, or hotels were included in the site, what was the estimated number of the population which would be displaced, what arrangements for their rehousing had been made, and whether the Government had considered the desirability of acquiring the site of the Foundling Hospital which was in the immediate vicinity and of approximately the same area, but had the advantage of not being intersected by roads or subject to leases, and would not involve the rendering homeless of many *families but would enable the trustees of the hospital to* remove their children to the country, as they were anxious to do —Mr FISHER replied In view of the fact that the matter is still under negotiation and the purchase is not yet actually completed, I am not in a position to make any statement as to the price proposed to be paid to the Duke of Bedford A full description of the site, including an enumeration of the number of houses on it and the dates of the termination of leases, has already been published As the great majority of the leases do not fall in until 1923 and after that date, no immediate provision for rehousing is necessitated After full consideration of all the relevant circumstances the Government decided that the Foundling Hospital site was less suitable for the purpose than the site behind the British Museum

Sir W DAVISON asked whether the right honourable gentleman was aware that the Senate of the University had already expressed a preference for the Foundling Hospital site as compared with the site behind the British Museum belonging to the Duke of Bedford, and would he inform the House why the Government were endeavouring to force the University to accept a site which was more expensive and less suitable to the University —Mr FISHER I am perfectly aware that many years ago when the London University question was in an entirely different position the Senate of that University came to that conclusion, but the Government has no doubt that as between the two sites the site now selected and offered to the University is preferable, first, because of its proximity to the British Museum the greatest repository of literary study in the world, secondly, because of its proximity to University College, and thirdly, because of its more central position The Government are not attempting to force the University to accept the site They may accept or decline it —Sir J D REES Will the cost in either case fall upon the public funds? Is it absolutely necessary to incur any such charge at the present time?—Mr FISHER It is perfectly true that the cost will fall upon the public funds, but it is offset by the value of the site and buildings at present occupied by London University in the Imperial Institute, and King's College, which will be liberated

Government and Voluntary Hospitals

Mr LEONARD LYLE asked the Minister of Health whether it was proposed to create a new hospital service to which the municipalities must cooperate with the State, and what was the exact policy of the department towards existing voluntary hospitals on the one hand and towards general hospital provision on the other —Dr ADDISON replied It is not intended that the Government should take over voluntary hospitals but I cannot undertake within the limits of a reply to a Parliamentary question to discuss the exact relation of voluntary institutions to the general scheme of public health services —Mr LYLE May I ask whether in view of the financial position of the voluntary hospitals to day the right honourable gentleman will consider the advisability of issuing a statement of policy at an early date?—Dr ADDISON replied We are giving the matter our attention from day to day, and I hope that I shall be able to make a satisfactory statement before long

Appointment of Women Doctors

Mr A T DAVIES asked the Minister of Health the result of his representations to the authorities of Sheffield street Hospital for Women Clare Market, W C 2, with reference to the appointment of women doctors as medical officers and assistant medical officers respectively —Dr ADDISON replied I am in communication with the authorities of the hospital in regard to this matter, but I have not yet received their reply

Administrative Posts at Health Ministry

Mr A T DAVIES asked the Minister of Health how many administrative posts in the Ministry of Health were held by men at a salary of over £500.—Dr ADDISON replied The number of administrative posts, including within this definition posts strictly defined as executive in the Ministry of Health held by men at a salary of over £500 is 103

Welsh Board of Health

Sir J CORY asked the Minister of Health what officers had been appointed to constitute the Welsh Board of Health, and what special functions each was to fulfil —Dr ADDISON replied The Welsh Board of Health is at present constituted as follows Sir Thomas Hughes, Chairman, Dr Llewellyn Williams M C (Medical Member); Mr John Rowland, M V O, C B E (Deputy Controller of Insurance for Wales), Mr A Lloyd Thomas (Housing Commissioner), Mr Percy Watkins (Secretary, Administrative Officer for Public Health and ex officio member of the Board)

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

NOTES ON
PSYCHOANALYSIS AND PSYCHOTHERAPY.[1]

BY SIR JAMES CRICHTON-BROWNE, M.D., LL.D., F.R.S.,
LORD CHANCELLOR'S VISITOR IN LUNACY.

PART I.

I WOULD acknowledge first our debt to psychoanalysis for having induced us to take a more psychical and a less material view of insanity, and for having insisted on the importance of tracing it back to its earliest manifestations. The illuminating discoveries of the last 90 years—I date from Marshall Hall—in the structure and functions and pathological changes of the brain and nervous system have concentrated attention, not exclusively but perhaps too much, on the somatic relations of insanity. It is well, therefore, that we should be recalled to the psychical factors in insanity. The pronounced nature of the psychical symptoms in a large majority of the cases brought under our observation in asylums, and their obvious dependence on coarse material changes, may have accustomed us to rest too generally content with these, and to fail to follow up fully in another and much smaller class of cases, clues which might conduct us to the purely functional disorders out of which the insanity has arisen.

Psychoanalysis Not a New Method.

But while gratefully appreciating the impetus given by psychoanalysis to the diagnosis of insanity by experimental methods and to ætiological research, I cannot admit that its methods are novel, or that there has ever been a time when such of them as are not objectionable have not been in use in our asylums. Hypnosis and crystal-gazing, association tests, and free association have certainly not been in vogue, but in every case some effort has been made by repeated skilled interrogation, by confidential discussion, by appeals to the emotions, by the stirring up of memories, by the observation of conduct, and even by the interpretation of dreams (Maudsley suggested that patients should be set to keep noctuaries instead of diaries), to get at the cause of the altered mental mechanism. It is not correct, as has been alleged, that in psychology, up till now, it is the intellectual factors of mental activity that have been almost solely considered, while emotional and instinctive states have been overlooked and neglected. An ample refutation of that will be found in the writings of the phrenologists, of Dugald Stewart, of Thomas Brown, of Alexander Bain, of Laycock, and of a score of others. While in medical psychology delusion has, perhaps, assumed an unduly prominent place owing to its convenience as a fact indicating insanity in all legal documents, states of exaltation and depression, blunted sensibility and perverted feeling, impulses and morbid appetites, obsessions and phobias of all kinds have bulked quite as largely as delusions in case-book reports. It is at what are called subconscious mental states that medical psychologists have stopped short, simply because such subconscious mental states are beyond direct scientific observation, and are matters of inference or speculation. Our knowledge of the existence of subconscious mental states is obtained, as in the case of a simple reflex act, by watching their physical effects. Psychoanalysis does not give access to the unconscious, but it ransacks the memory for its hidden stores and expatiates in supposititions, complexes, and mythical conflicts. The question comes to be whether its explorations are really worth while. Life seems a little too short for psychoanalysis. The examinations are, we are informed by Jung, laborious and often fruitless, and require almost unlimited time. A case is described by Jung in which two hours were expended in extorting from a young woman labouring under dementia præcox that she had seen a man with whom she had fallen in love, and that when a girl of 16 she had met when out walking an elderly idiotic woman whom she had provoked to obscene behaviour, and the result of all this protracted probing was that the patient, who was judged to have suffered from regret and remorse in conflict with religious conversion, "improved considerably." Dr. Stoddart tells us that "not only is the technique of psychoanalysis extremely difficult, requiring years of practice to obtain proficiency therein, but each individual case requires an enormous time. Even in the hands of the great masters of psychoanalysis the shortest cases take an hour a day for three months, and some take an hour a day for three years."

Doubtful Superiority to other Methods.

Onerous and enervating as must be the practice of psychoanalysis and the acquirement of its technique, our asylum medical officers would not grudge the time and toil required for it if it yielded better results than the methods of diagnosis and treatment hitherto in use, but on that point we have no conclusive evidence. There are no trustworthy statistics bearing on it. No doubt a large number of patients suffering from psychoneuroses have recovered rapidly under psychotherapy, and this has been especially notable in patients suffering from war-induced psychoneuroses; but it is to be noted that these cases have for the most part been of a mild description, of emotional origin, and of recent date, and that similar recoveries have taken place without any psychotherapeutical treatment and under other kinds of treatment than the psychotherapeutical; some of the war psychoneuroses came and went, as it were, of their own accord. Many men affected by them have returned to the front after few days at a base hospital and such rough-and-ready psychotherapy as could be there supplied—namely, a little friendly exhortation and good advice—and many who have been sent home have recovered promptly under autotherapy, or the exercise of their own common-sense. Readjustment to reality in such cases has been speedily effected on withdrawal from the poignant situation in which the mental disturbances arose, and a glass of wine has sometimes facilitated the readjustment. One of the ablest advocates of psychoanalysis in this country, Dr. Ernest Jones, has said: "Even if it were possible, I see no reason why psychoanalysis should be undertaken in the majority of cases, for they can be cured in much shorter ways"; and another equally able advocate —Dr. Bernard Hart—has said: "Psychogenic disorders are not only capable of being favourably influenced by suitable psychological methods, but are capable of being unfavourably influenced by these methods when wrongly used." We have, as yet, no reliable information as to the subsequent history of shell-shock cases diagnosed by psychoanalysis and treated by psychotherapeutical procedure. How many have remained well, how many have relapsed, how many have ended in suicide, how many have, by circuitous routes, found their way into asylums? We must wait and see before we can appraise the merit of this much-vaunted modern innovation.

Certain Objections.

Nor is there, I think, any great call for a treatment irksome to those carrying it out, distressing to many patients, sometimes strongly resented, of problematical benefit, and occasionally injurious in its effects. Is not much of this psychoanalytical boring quite superfluous? An elaborate investigation of the skeleton and orthopædic apparatus is not of much assistance in the case of skin disease, and a resurrection of long-buried psychical experiences is unnecessary in a great majority of mental ailments. Reports of psychoanalytical successes sometimes suggest the waste on trivial cases of a great deal of psychological ammunition.

Psychoanalysis in moderation, in connexion with our old and well-tried methods of clinical observation and research may be very useful, but, pushed to an extreme, and finding for all mental troubles a background of incestuous thought, of jealous, masochistic, sadistic, or homosexual emotions, it becomes itself an offensive obsession. Freudism, notwithstanding the diligent efforts made to acclimatise it, will, I feel sure, never take root in this country. Sexual symptoms have never been ignored by British alienists; but they must not be invented as they are when the libido is lugged in at every turn of thought. Psychoanalysis is itself a conflict of complexes, for I find amongst its adherents divergences in theory and practice that are irreconcilable. The psychoanalysts ignore altogether the finalistic ideals which are far more dominating and characteristic than the basic instincts amongst which they burrow. The instinct of self-preservation is, of course, primary, because without it there could be no other, but it is only in proportion as it is linked up with the sentiment of other preservation or altruism that civilisation has advanced. We presume in a man all the ordinary human instincts, propensities, emotions, in varying amount and individual combination, but as long as they lie latent we know nothing about them; it is only when they express themselves in action that they come into our ken. There is a risk that in exploring for sexual rudiments we may plant the seeds of the very growth for which we are in search, and delusions of a sexual or obscene character are about the most persistent and dangerous encountered in the insane.

The main objection to psychoanalysis as at present presented to us lies, I think, in its over-valuation of mental conflicts and emotional states in the production of the psychoneuroses and of the efficacy of immediate personal legerdemain in their removal. The psychogenic factor has been strongly in evidence in the war, but even where it has appeared to be solely responsible for the nervous or mental breakdown in presumably neuro-potentially sound persons we may depend upon it that the way was almost invariably prepared for it by hereditary predisposition or acquired habit, and that cooperative physical factors, such as fatigue or toxæmia or exhaustion from shortage of food or loss of sleep have also been at work The psychoneurosis, however set up, had an anatomical substratum, however slight or transient, for we must always bear in mind that complete mental and neural parallelism upon which Hughlings Jackson so strongly insisted The psychoneuroses are most conveniently explained in terms of psychology, are sometimes more accessible on the psychical side, and disappear under psychical treatment, but they can also be pictured as diverted nerve currents, can be thus approached, and pass away under treatment that restores nerve tone In most of the cases in which psychical treatment has availed there have been coincident with it changes in physical surroundings, diet, drugs, &c , that have, perhaps, had some share in the favourable issue Without in any way depreciating psychical treatment, I would say that, notwithstanding all the disclosures of psychoanalysis, the alienist physician will still be right in each case in regarding the physical ætiology as of primary importance The purest of the psychoneuroses are apt to set up a recurrent habit, and, if unrelieved, to run on into structural degenerations that are beyond the reach of psychical medication

---

[1] Being an overflow from the Maudsley Lecture delivered before the Medico-Psychological Association of Great Britain and Ireland on May 20th, 1920.

Psychic and Physical Factors in the Causation of Insanity

Psychogenesis is patent enough Who has not witnessed the profound depression induced by a great sorrow, or the joyous excitement that has followed on a stroke of good fortune, and what medical man has not occasionally seen the undue prolongation of these and their intensification into mental disorder? With the general public psychogenesis holds the most prominent place in the ætiology of insanity The relatives of the insane constantly ascribe their illness to some particular worry or distress, even when the disease is general paralysis or of obviously organic origin, and medical men have certainly never overlooked psychogenesis or the enthymic causes of insanity arising from impressive or exhausting thought, feeling, or emotion But the clearest demonstration of a psychogenetic starting point and of a connexion between it and the psychical symptoms in a case of mental disease should never render unnecessary a thorough somatico analysis The bodily conditions associated with the mental failure should be closely investigated, for amongst them may be found the key to recovery. Intestinal stasis and putrefactive changes in the alimentary tract with the absorption of toxins from the mucosa are often responsible for hypochondriasis, which may merge, in those of neurotic temperament, in melancholia, if suitable treatment is not resorted to No one can peruse the treatises on insanity of the first half of the last century without remarking that the physicians of the period did get wonderfully good results in certain cases by purgation. Pardo has shown, I think, conclusively that neurasthenia and some mental disorders occur in direct association with indoxyluria and disappear when the elimination of indoxyl is reduced from 10 to 20 per cent above normal to zero I have lately had an opportunity of seeing the notes of some cases under the care of Dr B. H Shaw at the Stafford County Asylum, in which attacks of delirium, confusional insanity, and melancholia, synchronising with acetonuria, yielded rapidly to an alkaline treatment The toxins formed in the cerebro spinal neurons subjected to stress—cholin, phosphoric acid, and particularly neurin—are highly poisonous substances, and upset mental equilibrium They excite the thyroid to supra normal activity, and the thyroid hormone, when produced in excess, breaks down fatty bodies in nerve and brain cells, thus accounting for many morbid, nervous, and mental phenomena As Sir Frederick Mott has pointed out, it is probable that changes in the secretions of the thyroid and other ductless glands, causing a disturbance in the hormone balance, may not only predispose to mental instability, but actually induce it It is probable also that disturbances in the sympathetic and autonomic nervous system are signalised by psychical disorders Incipient tuberculosis and the sequelæ of typhoid fever and of dysentery are often provocative of mental disease I am under the impression that in many cases of the psychoneuroses a study of cutaneous hyperæsthesia might have been even more instructive than psychoanalysis

Suggestion in Therapeutics

It will not be maintained that in cases of the kinds just mentioned, in which an adequate physical factor is at work, much benefit, pending its removal, could be derived from the most assiduous use of suggestion, persuasion, or re-education The physical conflicts must be stopped before the mental ones can be assuaged Attempts at the psychical dislodgment of the disorder will be futile until its physical foundation is removed Of course, psychical remedies should never be neglected They are as old as the hills Job's comforters tried them on, but the danger is that the use of the principal remedies in the psychoanalytical pharmacopœia are very apt to be divorced from medical guidance and control, and to be exploited empirically In psychoanalysis the cross examination that is to elicit a man's past transgressions might be more adroitly conducted by a barrister than a medical man, and in psychotherapy persuasion might be more persuasively urged by a clergyman versed in scruples of conscience and dialectics than by a man trained in the dissecting room and bacteriological laboratory That potent agent suggestion, of the sway of which every notorious public event affords examples, and on which the psychoanalyst largely relies, is the mainstay of the quack whose advertised triumphs are not all fictitious; very salutary effects are exerted by his confident predictions and startling examples, and I have no doubt that his grateful patients who are not frauds are chiefly neurotic subjects The same is true, to some extent, of Christian Science, and of Lourdes, which has been the citadel of suggestion in our times Extreme susceptibility to suggestion and to hypnosis implies a lowering of resistance in the highest nerve centres and an enfeeblement of the will, while in the healthy and well balanced man the range of suggestion is strictly limited

> O! who can hold a fire in his hand,
> By thinking on the frosty Caucasus?
> Or cloy the hungry edge of appetite
> By bare imagination of a feast?
> Or wallow naked in November snow
> By thinking on fantastic summer heat?

But the high grade neurotic subject, the fakir or the devotee, can do all these things, or thinks he can, and the mildly mentally afflicted can sometimes, by suggestion, be beguiled out of their fantasies and back into rationality The strong man is reasonably suggestible, but the hysterical girl responds to every hint

(*To be continued*)

FAMINE RELIEF IN THE UNITED PROVINCES OF AGRA AND OUDH, 1918-19

THE marked deficiency of rain throughout the United Provinces of Agra and Oudh during 1918 had the natural result of diminishing the yield of food crops, only 60 per cent of the early and 40 per cent of the late rice crops were obtained compared with the average, maize yielded only 55 per cent and millet only 40 per cent The spring yield in 1919 was only 61 per cent of the average To complicate matters from the health point of view there was not only a general disturbance of economic conditions on account of the war, but, in addition, a disastrous epidemic of influenza, which carried off a large number of able bodied labourers and left many dependents without means of livelihood The Lieutenant Governor, Sir P Harcourt Butler, took a bold course, and decided that the policy to be followed should be one of liberal suspensions and remissions of revenue, combined with some relief to those who had been left destitute A sum of no less than 200 *lakhs* of rupees (say £1,333,000) was given in advances for cattle, fodder, well construction, in aid of the sugar cane crop, &c Moreover, large remissions of revenue were granted, or its collection suspended Mr Percy Harrison was appointed Famine Commissioner The Famine Code, embodying the accumulated experience of many previous similar visitations, was found to be an almost complete guide to the necessary operations In this famine, in accordance with previous experience—

> "It has been proved beyond any question whatsoever that the testing of the necessity for relief is absolutely essential There is no matter in which the idiosyncrasy of individual officers requires to be so closely checked as in the matter of the existence or otherwise of distress requiring relief "

In the hill districts of Garhwal, where there was a large demand on the local stocks of food by pilgrims visiting the shrines of Kedarnath and Badrinath, the main difficulty was how to transport food in sufficient quantities to the remote and inaccessible homes of the people who required it Grain depôts were established under official management, and the pilgrim route was closed

Measures of Utility

In regard to the United Provinces generally various measures of real utility, such as the reclamation of waste lands in Etawah and construction of water storage works in Bundelkhand, were undertaken with success; and in very many instances native gentlemen gave large sums in charitable relief An important part of the work consisted in the procuring of a supply of fodder for cattle in the areas affected Private traders were encouraged by the grant of concessions on rail transport rates, and about double the quantity so obtained was supplied by official arrangements through the Forest Department from the State forests in Dehra Dun, the Tarai, and elsewhere The experience gained on this occasion will probably result in precautionary arrangements being made for the speedy supply of fodder in any subsequent occurrence of famine in these provinces As districts maintain programmes of works to be carried out on the occurrence of a famine, so might the Forest Department maintain programmes for famine fodder operations, with depôts, railway siding accommodation, &c., always available. Power presses for fodder are recommended, as by their use only half the amount of rolling stock would be required for transporting a given quantity of hay. All necessary equipment of this sort should be regarded as an insurance against famine.

This narrative of the measures adopted for the relief of famine by Mr. J. D. Elliott, Secretary to Government, concludes with an acknowledgment of the services of numerous private individuals in the administration of district relief funds and of their public-spirited assistance in many ways. We may be allowed to add that it also affords abundant evidence of the practical genius of our countrymen in dealing with conditions of the greatest difficulty and emergency that can be imagined; and that if any justification for the British Raj in India were necessary, it would be found in ample measure in the plain "Narrative and Results of the Measures Adopted for the Relief of Famine during the Years 1918 and 1919" in the United Provinces of Agra and Oudh.

"QUEEN ELIZABETHES ACHADEMY."

A PAPER published in the *Bristol Medico-Chirurgical Journal* of March, 1920, by Mr. L. M. Griffiths deals with a little known tract entitled "Queen Elizabethes Achademy," the subject of which is "The erection of an Achademy in London for educacion of her Maiestes Wardes, and others the youth of nobility and gentlemen." The author was Sir Humphrey Gilbert, and he was apparently led to his proposal by the very poor opinion which he held of the Universities; "At this present, the estate of gentlemen cannot well traine up their children within this Realme but eyther in Oxford or Cambridge whereof this ensueth; first being there they vtterly lose their tymes yf they doe not follow learning only. For there is no other gentlemanlike qualitie to be attained. Also by the evill example of suche, those which would apply their studies are drawen to licentiousnes and Idleness; and therefore it were every way better that they were in any other place than theare." Gilbert's Achademy provided for instruction in subjects which practically coincide with The Seven Arts, together with Physic, Surgery, Law, Divinity, Cosmography, Heraldry, and foreign languages. Moreover, the scholars were taught the use of "the great horse." Physic and Surgery were to be taught in English, not in Latin, and it is interesting to note that as regards the library Gilbert anticipated the rule which holds at the Bodleian and the British Museum. "All Printers in England shall be for ever charged to deliver into the Liberary of the Achademy, at their owne Charges, one copy, well bownde, of euery booke, proclamcion, or pamflette, that they shall print." Gilbert's Achademy never materialised, but in the year 1700 an attempt was made by one Mr. Lewis Maydwell to obtain a Parliamentary grant to enable him to run an Academy for teaching "the Riding of the Great Horse and some other gentil Accomplishments" which he claimed were not to be had in the Universities. Mr. Maydwell's scheme was severely criticised by the then Savilian Professor of Geometry at Oxford, Dr. John Wallis, who in a most amusing letter stated that everything necessary for a gentleman was taught, or could be taught, at Oxford, and hinting, not obscurely, that Mr. Maydwell's scheme was only designed to make himself rich. It cannot be said that physical exercise is now neglected at the Universities, though it is not yet part of the University Course. Dancing, which is undoubtedly a most useful exercise, used to be part of the curriculum at Eton, the last boy to learn it, if we remember right, being the late Dr. Pusey.

ANALYTICAL NOTES ON DRUG SUPPLIES, 1914–1919.

THERE are some interesting disclosures in "Evans's Analytical Notes," covering the period 1914 to 1919, issued last week in pamphlet form by Messrs. Evans Sons Lescher and Webb, of 56, Hanover-street, Liverpool. These useful notes were published annually prior to the war, but the issue was discontinued in 1914. Amongst some of the items in this recent number calling for notice in regard to the purity of drugs are the following. Acetyl salicylic acid of English manufacture is reported to be equal in quality to anything that was produced abroad. Many samples of amyl nitrite failed to comply with the requirement of the B.P. that 90 per cent. should distil below 100° C. Arsenical impurity was found in samples of commercial borax and boric acid. Chloroform has under the tests made given uniformly satisfactory results according to B.P. requirements. Arsenic and lead were of constant occurrence in samples of cream of tartar. Acetone was found in samples of ether. The viscosity of paraffin liquidum was found to vary in the specimens examined from 71° to 300° (Redwood). The need for official standardisation on this point is obvious, as we indicated in a special inquiry upon the subject (THE LANCET, Oct. 2nd and 16th, 1915). Boric acid and sugar were found in veronal. Samples of potassium iodide contained a considerable quantity of potassium chloride. Many other examples could be quoted, but the foregoing show generally the interest of the compilation in addition to which some improved methods in regard to analytical procedure are described.

FIRST-AID GUIDES.

Colonel R. J. Blackham, Assistant Director of Medical Services at Chatham, and the author of several well-known manuals of first-aid and nursing, has compiled an excellent series of pocket guides to first-aid treatment, which are being published by Messrs. Dale, Reynolds and Co., 46, Cannon-street, London, price 6*d*. each. Two of these, No. 2 Hæmorrhage, and No. 3 Insensibility, lie before us, the form being a four-page card measuring 3½ in. by 5½ in. The instructions are printed in tabular form and in non-technical language, those in regard to hæmorrhage giving the signs of bleeding, the general first-aid treatment, and the methods of applying pressure, while those for insensibility set out its various kinds, the methods of recognising them, and their treatment. These cards should prove helpful to both instructor and pupil; to the first as a convenient form of lecture notes, and to the second as summaries of first-aid teaching which can be carried in the pocket and consulted at odd moments. In factories where the full-time doctor is not employed the distribution of such cards among the workers might be the means of saving life; and in any case it would help the patient till the arrival of the doctor.

THE ART OF PRACTICE.

WE have received a pamphlet entitled "The Management of Patients: Success in Practice," wherein an attempt is made to assess the relative importance of manner and professional skill in the successful treatment of private patients. The conclusions reached are greatly to the disadvantage of skill when divorced from other factors. The pamphlet is issued by the Post-Graduate Society, Thanet House, Temple Bar. There is attached an application form for a "course," in the form of a book, on tactics and therapeutics, which is compiled by an unnamed authority.

Harrovian will have to take legal advice on the whole case. As he sets it out, the Act would seem to apply.

Communications, Letters, &c., to the Editor have been received from—

Goulstonian Lectures

ON

THE PRINCIPLES OF MEDICAL SCIENCE AS APPLIED TO MILITARY AVIATION.

Delivered before the Royal College of Physicians of London.

BY J. L. BIRLEY, C.B.E., M.B., B.CH. OXON., F.R.C.P. LOND.

LECTURE III.*—WAR FLYING AT HIGH ALTITUDES *(continued)*.

Delivered on March 16th, 1920.

MR. PRESIDENT AND FELLOWS,—There still remain to be considered one or two points in connexion with high altitudes before we can pass on to the main subject of this lecture, the importance of the ear in aviation.

PHYSICAL FITNESS AND HIGH FLYING.

The bodily reactions which high flying entails are comparable in some respects to those with which we are familiar during muscular exertion at sea-level, their main object being to provide oxygen in quantities sufficient for the needs of the body. It was certainly our experience to find that those individuals who had long been accustomed to take vigorous exercise resisted the effects of altitude better than their more sedentary companions.

It can also be readily understood how utterly unsuited for high altitude work is the individual whose central nervous control has either never been properly developed or has been weakened as the result of strain and fatigue. The shallow breather whose ventilation is both inadequate and uneven[1] is already in an anoxæmic condition by reason of his breathing, while the individual whose pulse and arterial pressure are abnormally sensitive to exertion or excitement has no reserves to fall back upon.[2] The subject of the "effort syndrome" is, in fact, in much the same physical state in the hospital ward as is the healthy pilot at 20,000 ft.

THE CLINICAL EXAMINATION OF CANDIDATES.

Brief attention may here be made to the medical examination of candidates for the flying service, since one of the most important questions which the examiner has to decide is whether the candidate is fit for high flying. I have stated in a previous lecture that in my opinion it was inevitable that the standards devised by the Candidates Examination Board were productive of more criticism than those which they replaced. My reasons for thinking so are that something was being attempted which had not seriously been attempted before—viz., to standardise the normal individual, or even to pick out the superman. It would seem that we have no settled conception of what we mean by a normal individual, or else that the range of normality is so great as to permit of us having different conceptions.

It was found as a matter of experience that those who stood the stress of service well conformed to the standards of circulatory and respiratory fitness laid down by Flack.[3] Their pulse-rates tended to be comparatively slow at rest, reacted quickly and effectively to changes of posture and to moderate exercise, and quickly returned to normal after exercise. Similarly the blood pressure showed no excessive response to exercise or emotion. On the respiratory side individuals with high vital capacity, low consumption of air per minute,[4] a slow rate of breathing, power to hold the breath for over a minute, and good expiratory force demonstrated their suitability for work at high altitudes. The ability of an individual to sustain by an expiratory effort a column of mercury at 40 mm. for any length of time, though more difficult to interpret, involving as it does an obstacle to the return of venous blood to the heart, was, nevertheless, correlated with physical fitness and mental resolution. The performance of an individual subjected to these tests was appreciably diminished by anything which lowered his physical health, such as an attack of influenza, scabies, &c. But the condition which more than any other was productive of an inability to pass these standards was that which we have already studied under the name of anxiety neurosis. When, therefore, we make use of these tests we must remember that the subject under examination possesses a cerebral cortex, and we must not be encouraged into talking too glibly about "cardio-vascular debility" and "respiratory weakness."

It has recently been shown[5] that definite relationships exist between vital capacity and body surface, body weight, stem length or sitting height, and chest measurement; and it seems justifiable to hope that the results to be obtained by a wider application of these measurements and of the principles on which they depend will help us to a fuller and clearer understanding of what we mean by a normal individual.

TEMPERATURE.

The cold experienced at high altitudes is very great at all seasons of the year. On a hot day in July, when the thermometer on the ground may be registering 80° F., at 20,000 ft. it is at, or just below, zero, while in January at this height there are often more than 60° of frost.

It is well known that cold increases the O_2 intake and CO_2 output (but not the nitrogenous metabolism) by a reflex stimulation causing shivering and restlessness, and this action is reflected in the inclination to take exercise in cold weather.[6] If, however, all movements are avoided no increase in the respiratory exchange takes place.[7] The flying officer is handicapped in the air by his relative immobility, and the external cold tends to aggravate his anoxæmic condition. Incidentally, when individuals are experimentally subjected to low O_2 pressures they frequently complain of coldness of the extremities.[8] The aim of clothing is, of course, to maintain a high and constant temperature between the body surface and the nearest layer of clothing, and there can be no doubt that the great improvements effected in this connexion during the war largely increased efficiency in the air. Difficulty must always be experienced in protecting the face and hands, the latter because heavy flying gloves have frequently to be discarded temporarily for the purpose of taking photographs, fighting a gun, clearing a jamb, &c.; to touch metal at −30° F. with the unprotected hand must inevitably cause acute frost-bite. This difficulty was in some degree overcome by the wearing of electrically heated gloves. Pilots flying at high altitudes by withdrawing their heads momentarily from the protection afforded by the windscreen often secured in this way a welcome stimulation, the action of the rush of cold air being, no doubt, a reflex one from the skin of the face to the medullary and higher centres.[9]

The Effect of Altitude on the Ear.

Slight but temporary deafness after landing has long been a matter of common knowledge among aviators, and was usually attributed to the noise of the engine. This symptom, however, especially after the introduction of the fast scout machine, began to be frequently associated with discomfort or actual pain in the ear, more often unilateral, and a feeling of unsteadiness, both of which might persist for some hours, while in a few individuals the pain was so great that they had to discontinue flying altogether. It seemed probable that this condition was referable to a difference of air pressure on the two sides of the tympanic membrane. It was shown by Scott[10] that inspection of the ear under these circumstances immediately after landing reveals a fundus bright red owing to engorgement of the vessels in the tympanic membrane, while in extreme cases the membrane is strongly invaginated into the tympanum and closely moulded over the ossicles. These changes are referable to the patency or otherwise of the Eustachian tubes. During ascent the rise of relative pressure in the tympanum is usually sufficient of itself to open the Eustachian tube and so to bring about equalisation of pressure on the two sides of the drum. During descent, on the other hand, especially if rapid; when the excess of pressure is on the outside of the drum equalisation can only be effected by some muscular effort which will stretch the openings of the tubes and allow air to pass up. In the normal individual with patent Eustachian tubes this can be effected by repeated swallowing, a movement which is facilitated by keeping a piece of chewing-gum in the mouth and rendered difficult by the dryness of the throat which results from breathing the cold, dry air at great altitudes with the mouth open. It can also be effected by imitating the first part of the act of yawning, or by repeated auto-inflation of the ear by Valsalva's method. During a steep and prolonged "dive," at a speed of perhaps more than 200 m.p.h., equalisation of pressure may be impracticable. Owing to the [illegible] of the curve of barometric pressure in relation to [illegible] this effect on the ear is greater when descending

---

* Lectures I. and II. were published in THE LANCET of May 29th (p. 1147) and June 5th (p. 1205) respectively.

10,000 ft. to ground level than it is from 20,000 to 10,000 ft. In individuals where there is definite Eustachian obstruction, whether due to a cold in the head or to some other cause, a descent of several thousand feet may cause not only pain in the ear on the affected side with pressure sensations in the head and deafness, but hæmorrhage may occur or even actual perforation of the drum. Airmen with large bilateral perforations are, of course, immune to these symptoms.

In cases of unilateral Eustachian obstruction, where an officer may have complained of actual vertigo while flying, and landed with unsteady gait, earache, headache, and nausea, Scott[11] has further observed nystagmus, forced movements, unnatural position of the head, and other disturbances of equilibrium. All these disturbances can be relieved by successful catheterisation of the obstructed tube. The condition is clearly related to differences of air-pressure in the ear on the two sides, with corresponding differences of endolymph pressure, and in consequence a divergence of information from the vestibular receptors of the two sides with resulting disturbances in consciousness. It is further possible that the profound and rapid changes of temperature experienced when flying may aggravate the condition by effecting a modified "caloric test" of unequal intensity on the two sides.

This regulation of pressure in the ear by means of the Eustachian tubes is by far the most important practical point connected with the ear in flying. Its importance, however, has been largely overshadowed in favour of the greater but more hypothetical interest aroused by the consideration of the internal ear as the organ of balance or of motion-sensing.

THE QUESTION OF BALANCE IN THE AIR.

Few who have ever flown can watch the graceful evolutions of a bird on the wing without wonder mingled with envy. Comparison between the bird and the distant aeroplane is irresistible, and knowing that the latter is controlled by a pilot, although we cannot see him, we instinctively ask ourselves, On what aspects of function do the seemingly bird-like qualities of the pilot depend? It has elsewhere[12] been stated that, "in order to preserve the wonderful accuracy necessary for controlling an aeroplane the pilot relies pre-eminently on his ear-balance sense." We must now investigate the correctness or otherwise of this view.

THE ANATOMY OF THE LABYRINTH.[13]

The internal ear consists of an auditory and a vestibular portion; it is only with the latter that we are concerned.

The membranous labyrinth lies slung in its bony counterpart, the osseous labyrinth, from which it is separated by a fluid called perilymph. It consists (*a*) of two membranous sacs, the utricle and saccule, which lie inside that portion of the labyrinth known as the vestibule; and (*b*) of three semicircular canals. These canals are set in the three planes of space; the external or horizontal canal in the horizontal plane, and the two vertical canals in the vertical plane and at right angles to one another. The latter are usually termed the posterior vertical and superior vertical canals, the posterior canal of one side lying in the same plane as the superior canal of the other, and vice versa. Each canal has a large or ampullated and a small extremity, both of them opening into the utricle. The small ends of the two vertical canals, however, coalesce before entering the utricle, which therefore has five openings. The swollen end, or ampulla, of each canal contains the crista acustica or crista ampullaris, an elevated ridge protruding into the lumen of the ampulla crescent-wise and lying at right angles to the axis of the canal. The crista constitutes the nerve end-organ, comprised of hair cells 20μ in length, jutting out into the lumen of the ampulla, which like the other portions of the membranous labyrinth is filled with a fluid called endolymph. The fibres of the vestibular portion of the eighth cranial nerve end in arborisations round the hair-cells of the crista. The crista may be said to divide the canal into two portions, a short sinus portion toward the utricle, and a longer tubal portion comprising the rest of the canal. The utricle and saccule also contain two nerve end-organs, known as the macula of the utricle and the macula of the saccule respectively; these are histologically similar to the crista, except that instead of being raised they are flush with the surface, and the gelatinous membrane, or cupula, which overlies them contains a few small concretions of carbonate of lime, called the otoliths, which are not found in the cupula of the crista acustica.

EXPERIMENTAL PHYSIOLOGY OF THE LABYRINTH.

Flourens (1824–42)[14] was the first to show by experiments, chiefly on pigeons, that destruction of the vestibule and semicircular canals is followed by disturbances, not of hearing but of equilibrium. He further observed that the peculiar pendulum-like movements of the head in pigeons submitted to operation occurred in the plane of the canal transected, and was of opinion that the peculiar relation of the canals in the three planes of space was related in some way to their function. He concluded that—

> "In the semicircular canals there is an agency which restrains and moderates muscular movements; the vertical canals moderate movements backwards and forwards, the external canals moderate movements from right to left, and from left to right."

These brilliant researches made little impression, and it was not until Menière in 1861 described disturbances of equilibrium as a symptom of internal ear lesions that their significance was appreciated.[15] In 1870 Goltz[16] confirmed Flourens' results, while Crum-Brown,[17] Mach,[18] Cyon,[19] Breuer,[20] Ewald,[21] and Lee[22] made further classical contributions to our knowledge of the labyrinth. The interpretations of the results obtained by these different experimenters varied considerably, although the results themselves are fairly concordant. Both Mach and Crum-Brown, as a result of rotation experiments, concluded that man possesses a special sense of rotation, the peripheral sense-organ concerned being the semicircular canals. Breuer amplified this view and looked upon the semicircular canals as the organ for appreciation of rotational movements, while the maculæ of the utricle and saccule appreciate progressive movements. Cyon, again, advocated the view that the semicircular canals constitute the peripheral organ which subserves a sixth sense, the sense of space, on which are projected our additional space conceptions derived from eye, muscle, and skin.

Ewald (1892), a pupil of Goltz, was the first to provide experimental proof of the correctness of the assumption first put forward by Breuer, that the specific stimulus to the hair cells of the crista is afforded by the current of endolymph in the canals. By opening up one canal and connecting it with an air-pressure apparatus he demonstrated in pigeons that the movements of the head and eyes are always in the direction of the endolymph flow and in the plane of the stimulated canal. It is this discovery which has rendered possible the investigation of labyrinthine function in clinical medicine.

Ewald further demonstrated that in the horizontal canal a movement of the endolymph toward the utricle causes a reaction twice as strong as a movement away from it, whereas in the vertical canals the exact opposite is the case. This curious difference between the horizontal and vertical canals has no physical explanation, while its physiological significance is obscure. Ewald's discovery, however, that the strength of the reaction depends on the direction of movement of the endolymph in relation to the ampulla is of considerable physiological importance, since the ampullæ of the two-paired canals which lie in the same plane are so arranged that particles moving in the same direction in the two canals move toward the ampulla of one and away from the ampulla of the other. It therefore follows that for rotation in any given direction and in any given plane the total reaction will be evoked as to two-thirds from one canal and as to one-third from the other (paired) canal. Flow towards the ampulla of the horizontal canal evokes its principal function, flow away from it its subordinate function. "Each horizontal canal," to quote Lee, "stands to the opposite one in the same functional relation as each vertical canal to the one diagonally opposite; in both cases the principal function of the one being of the same *kind* as the subordinate function of the other." The fact of a double function (principal and subordinate) necessitates the assumption of the existence in each crista of two functionally different kinds of nerve-ending, and we must further assume the presence of two different "patterns" of central connexions corresponding to the two kinds of functional discharge.

As regards the more primitive part of the membranous labyrinth, all vertebrates except mammals have three otolith organs on each side—the utricle, saccule, and lagena. These organs bear to one another the same spatial arrangements as the semicircular canals, the macula of the utricle lying in the same plane as the horizontal canal, that of the saccule in the plane of the superior, that of the lagena in the plane of the posterior canal. In mammals the lagena is developed into the auditory cochlea. It is evident that by reason of the structural arrangements of these organs the incidence of the weight of the otoliths on the hair cells of the macula must vary according to the position and movements of the head with reference to the line of gravity. A movement in a straight line will not produce any current in the semicircular canals, since the influence of the inertia in the two halves of each canal will be found to be equal and in opposite directions. But linear movements of the head at their commencement and termination, or changes in the rate at which the head is moving, must cause some alteration *in the incidence of pressure exerted by the otolith on* its subjacent hairs These considerations form the basis of Breuer s hypothesis that the sacs (utricle and saccule) form the static and the canals the dynamic organ of equilibrium It must be remembered, however, as Lee points out, that, with *every movement*—i e , with every *change of dynamical* sensations—a change of statical sensations must also occur

The grosser effects of extensive labyrinthine destructions are well known When all three canals are cut on one or *both sides the animal shows, in addition to weakness and loss of muscular tone, a distressing inability to maintain* a normal attitude not only of its head, but of the whole body Any attempt to move results in violent movements necessitating the wrapping of the animal in bandages to prevent injury Pigeons with only one canal cut recover *completely in a few days*, with two *canals* cut they recover completely, as far as walking is concerned within a month, but exhibit an unwillingness to fly [23] With all six canals cut a pigeon may recover sufficiently to stand, walk, and feed itself, but it remains permanently unable to fly for more *than a few* yards, and then only in a struggling *fashion and a short distance above the ground*

CLINICAL EXAMINATION OF LABYRINTHINE FUNCTION

It is to the Vienna school of otologists and in particular to Barany [21] that we owe the application to clinical medicine of the knowledge gained by the experimental method Given (*a*) the position of the canals, (*b*) the direction of movement of the endolymph, and (*c*) the relation of this movement to the ampulla, we can by *effecting movements* of the endolymph investigate the responses *from* each canal, *remembering* Ewald's law, that the movements of the head and eyes are always in the direction of endolymph flow and in the plane of the stimulated canal

There are three methods by which we can stimulate the semicircular canal system (1) Rotation with sudden deceleration; (2) caloric (hot and cold water or air), and (3) galvanism. Here I propose to confine myself to rotation

Suppose, now, that an individual sitting in a chair, with the *head* 30° *forward* so as to put the two horizontal canals exactly in the horizontal plane, is rotated, the endolymph in the horizontal canals will be affected At first, owing to its inertia, the endolymph will lag behind, as the rotation continues it will catch up, and when rotation is suddenly stopped it will be carried along for a short time by its acquired momentum in the direction of the previous rotation

A *Nystagmus*

Considering first the *ocular phenomena*, the movements of the eyes which actually occur are to and fro movements, consisting of a slow and a rapid component It is the slow component which results *from excitation of* the hair cells of the crista, and occurs therefore in the direction *of the endolymph* flow The quick component is mediated by higher cerebral centres, and is abolished by narcosis [12] Somewhat unfortunately it is the quick component which for clinical purposes is taken as the index *of the direction of* nystagmus

Suppose, then that the individual is rotated with head 30° forward clockwise—i e , from left to right When rotation is suddenly stopped the endolymph will continue to the right, *the slow nystagmus will be to the* right, although clinically the nystagmus will be described as *being to the* left Further, endolymph flowing to the right in the horizontal canals moves away from the ampulla of the right side *and* towards the ampulla of the left Therefore, on deceleration *after rotation* to the right two thirds of the reaction is due to the left canal and one third to the right In other words, the labyrinth on the side opposite the direction of rotation is chiefly responsible for the reaction evoked when the *rotation is stopped* The vertical canals can be stimulated by rotation by placing the head *in* such a position that the two corresponding canals are brought into the *horizontal* plane Interpretation of the reactions after stimulating the vertical canals are more complicated, but the principles are the same—viz , *that the slow* component of the nystagmus is in the same plane and in the same direction as the endolymph flow.

In addition to nystagmus two other phenomena can be evoked by deceleration *after* rotation—namely, vertigo and forced movements

B *Vertigo*

Rotatory vertigo manifests itself in certain definite planes After rotation with the horizontal canals in the horizontal plane the *vertigo is in the horizontal* plane—i e , there is a sensation of turning round and round, which is not unpleasant After turning to the right (clockwise) the sensation is of turning to the left—i e , in a direction *opposite to the endolymph flow If now the individual is* turned with the head 120° forward, so that the vertical canals are influenced in the frontal plane, the vertigo is also in the frontal plane and if the head is kept down after turning the vertigo is in a plane parallel to the floor—i e , a sensation of *turning round and round If, however, after rotation the* head is raised the frontal plane becomes at right angles to the floor, and the sensation is one of "turning in the frontal plane" Now "turning in the frontal plane" is a matter of *doing "cart wheels"*, hence, what we *actually* experience is a sensation of *falling* in the frontal plane—i e , to the right or left Similarly if after turning with the head in the sagittal plane—i e , with the side of the head resting on the shoulder—the head is raised to the upright position, the sagittal plane or plane of rotation now becomes at right *angles to the floor*, and the sensation is one of "turning in the sagittal plane" Now "turning in the sagittal plane" is a matter of doing "somersaults", hence what we actually experience is a sensation of falling in the sagittal plane—i e , either backwards or forwards

It is no more, or less, difficult to understand why the vertigo after rotation in the horizontal plane is in a direction opposite to the endolymph flow than it is to understand why an image which is upside down on the retina is seen right side up by the brain In both cases it is essentially a matter of experience [25] When we turn the head to the right the *endolymph* lags behind and *moves relatively to the left* Experience from other receptive fields has taught us to associate such a movement of the endolymph with rotation of the head in the opposite direction If now the endolymph moves and the head remains still, we shall experience an *apparent movement of the head and* secondly *of* the body in the opposite direction, hence, when rotation to the right is stopped, the endolymph continues to move to the right and we feel as if it were turning to the left

C *Forced Movements.*

These phenomena are secondary to the vertigo and do not occur in its absence It is because we feel we are rotating, say, to the right *that* we past point to the left—i e , to the point *at which we imagine the object to be Falling may* be regarded as a past pointing of the entire body, and only occurs when the vertigo is in the frontal or sagittal plane

Before applying these facts to aviation, we may briefly summarise them as *follows* —1 It has been demonstrated experimentally that the semicircular canal system is capable of appreciating movements in the three planes of space, a function strongly suggested by its anatomical structure In view of this capacity the vestibular labyrinth must be regarded as part of the great *afferent* system which renders coordinated movement possible and maintains bodily equilibrium 2 The rotatory and other means of excitation introduced by Barany help us to establish the functional integrity or otherwise of the vestibular labyrinth and its central connexions

THE RESEMBLANCE BETWEEN A BIRD AND A PILOT

Returning to our opening analogy, it can at once be seen that the resemblance is artificial The bird flies itself, its deep receptive field constantly stimulated by the movement of the animal, and its cutaneous field freely open to excitation from the environment. The pilot flies a machine, more or less immobilised, with his cutaneous field to a great extent cut off from the environment *by the clothing necessary for maintaining his body warmth He obtains, however, valuable* information from the "feel of his joy stick," just as we by experience can feel a piece of dead bone at the end of a probe

But we have been further advised [19] that "to realise the importance of the ear in flying it is only necessary to consider a bird flying in a cloud"—i e , deprived of its sight *Here* I must confess to thinking that the phenomenon we are asked to consider under *ordinary circumstances* never occurs The quite remarkable degree of visual acuity possessed by birds especially by those with great ranges of flight (condor, vulture, &c) is proverbial, and the habits of *birds are peculiarly controlled* by the presence or absence of daylight, only by those species possessed of *a dark* adapted eye is nocturnal activity exhibited We must all have been struck by the seemingly complete absence of bird life on a *foggy* day On such a day in winter the gulls are not seeking *food* on Westminster Bridge, but are, so to speak, anchored to the water, while sea birds following in the wake of a steamer close up to and even alight on it immediately the vessel runs into a sea mist It is not here suggested *that a bird deprived of vision* is so handicapped as regards equilibration that it cannot fly, but *simply that* under these circumstances it does not fly The assumption that a bird can fly, relying exclusively on information derived from its labyrinth, remains an assumption. The flight of a bird is a highly coördinated activity, and after destruction of both labyrinths the degree of coördination necessary for flight is no longer possible. In other words, the results obtained by experiment are not evidence for the opinion that the labyrinth is *the* organ of equilibrium, but merely that it is *an* organ of equilibrium; or to borrow and transpose a phrase used by Dr. Hughlings Jackson: "To locate the damage which destroys equilibrium and to localise equilibrium are two different things."[26]

THE AFFERENT EQUIPMENT OF THE PILOT.

The ability of man to fly by night has been one of the main arguments adduced by those who contend that labyrinthine impressions are capable, almost unaided, of endowing the pilot with a "sense of position" in the air.

All flying officers, however, are unanimous in stating that at night "you have to see something." They maintain their position relative to the earth by means of a horizon—either the true horizon, or more often a false one between mist and sky, or by means of the moon or stars. Flying in pitch darkness is impossible, and by daylight in a cloud or fog all sense of position relative to the earth is lost, and one is apt to emerge from a cloud upside down, held in the machine by centrifugal force.

To get some idea of one's dependence on vision it is only necessary to fly as a passenger with bandaged eyes. In this connexion two points in particular are interesting. In the first place, I found I could appreciate with fair accuracy all movements with which I was familiar; that is to say, having recognised an initial change in direction, the end-result could be anticipated and correctly appreciated. But if evolutions took place with which I was totally unfamiliar, my loss of direction and position was complete.[27] Secondly, deprived of vision one instinctively seeks for other sources of information, which under ordinary circumstances pass unnoticed. These were, in the order in which they impressed me (I make no attempt to assess numerically their physiological significance): (*a*) auditory, the changes in note of the engine, the singing of the air through the bracing-wires; (*b*) cutaneous, air currents and sensations of warmth and cold on the two sides of the face, sensations produced by air currents under different parts of the clothing; and (*c*) pressure on the buttocks and soles of the feet.[28]

More recent tests carried out in Canada in which the pilot was blindfolded revealed his helplessness; unable to allow for the "torque" of the machine he flew in the arc of a large circle.[28]

VISION AS AN IMPORTANT FACTOR.

In reviewing, then, the afferent equipment of the pilot we are justified in placing vision in the forefront. It is by sight that he keeps a level antero-posterior plane by noting the position of the horizon relative to the radiator-cap, and by sight that he maintains lateral stability by noting the position of the wing-tips relative to the horizon.

But besides vision many other afferent impulses are doubtless involved, although several fail to pass the threshold of consciousness. To attempt to assess their individual worth in mathematical terms would appear as futile an undertaking as an attempt to give a numerical value to the importance of the tactile sensibility of the feet for walking. For success in flying or walking we primarily depend on those educative processes which we call experience.

The exaggerated influence claimed for the labyrinth is contradicted by the evidence supplied by deaf-mutes, since these individuals, with physiologically "dead" labyrinths, "can run and ride, dance and turn, hop and jump, and, presumably, could learn to fly."[10] It is only when we can partially suppress their visual and cutaneous sensations, as by immersing them under water; in other words, when we can approximate the conditions to those in which the labyrinth was originally developed—viz., the conditions of an organism exhibiting free motility in a fluid medium, that the deaf-mute behaves abnormally and loses all sense of direction.[29]

By blindfolding deaf-mutes and taking them up in the air attempts have been made[30] to demonstrate that without the aid of vision they have no "motion-sensing" perception. A careful scrutiny of the results of these experiments shows, indeed, that their ability to appreciate the direction of movement of the aeroplane is less than that possessed by normal blindfolded individuals. Such a result would be expected, since nobody can justifiably contend that the labyrinth of man is a vestigial organ with no useful function to perform. The adaptability of man, however, is one of his most characteristic features, and under ordinary conditions the deaf-mute can compensate for the absence of labyrinthine impulses; even in the experiments alluded to there is evidence that his ability to detect both the direction and extent of movement improved with experience. On the other hand, it is pertinent to observe that if we deprive a normal individual of his sight we at the same time gravely impair the utility of the labyrinth, for this organ controls the position of the retinæ in such a way that they conform to a plan with which experience has taught us to be familiar (v. infra). Moreover, it would appear in the highest degree improbable that an organ phylogenetically as old as the labyrinth should, so to speak, have had to wait for the advent of the aeroplane before the full extent of its utility could be demonstrated.

THE QUESTION OF VERTIGO.

It was a matter of everyday experience to come across officers who complained of giddiness while flying, and not unnaturally the part played by the internal ear in the production of this symptom was investigated.

The occurrence of vertigo as a result of labyrinthine excitation would appear to have been an obstacle to the proper conception of the functions of this organ. "Why look for a specialised organ," asks Cyon, "which would have the curious object of producing vertigo? Vertigo is a pathological phenomenon."[10] Rotatory vertigo, by which is meant a sensation of objects rotating in a certain direction, or of the body rotating in a certain direction, can be produced by disease, or in normal individuals by excessive excitation. Now the tests advocated by Barany help us to ascertain whether the vestibular paths are intact by noting the nature of the response elicited after excitation of each individual canal; at the same time it is absolutely essential to remember that the excitation employed, and the reactions consequently evoked, are altogether in excess of what is physiological. The crudeness of the method in no way interferes with its utility in disease, although were we to employ similar methods for testing other forms of sensation we should estimate the sense of touch by pinching and that of pain by torture.

But vertigo and its allied conditions, with their accompanying motor phenomena, can be elicited by means other than violent disturbances of the endolymph. It can be evoked by watching a rapidly moving object, as by looking at a waterfall, sitting in a room the walls of which are made to rotate, looking out of the window of a moving train, by producing an artificial strabismus, by moving about with the head in an unnatural attitude, and so on. A pigeon, for example, with its head tied down to its body becomes nearly as ataxic as one deprived of its labyrinth.[31] Vertigo, in fact, is an illusion due to disharmony of sensation. As a result of experience we have learnt to correlate the position of external objects and the position of ourselves with certain definite positions of the head and eyes. The picture of the external world is familiar to me in the erect position; if, however, I view it with my head between my legs I am presented with a picture which is unfamiliar, and my judgment of the distance from me of objects becomes erroneous. In a normal state of things the visual and other sensory impulses (auditory, tactile, proprioceptive) which go to make up the coördinating machinery are, with reference to the events in the external world which are giving rise to them, in accord with each other. If, however, these impulses are not in accord, if I receive information from one source which is contradicted by that received from another, my brain will not know which to believe, and trying to believe both I shall be in a dilemma. The simplest example of this is that produced by artificially altering the position of one eye[32]; impressions from the retina and ocular muscles fail to correspond, and to quote Hughlings Jackson,[33] "the eyes tell lies to the feet; they see things in places where the feet fail to find them." The converse is also true. Thus the deaf-mute, no matter how violently he is rotated, experiences no vertigo or disturbance of equilibrium; there being no response from his labyrinth, there is no disharmony of impulses and no dilemma. We must also recognise that violent stimulation in any one field may evoke such a violent response from that field that the coördinating centres fail to tone it down to conform with impulses originating in other receptive systems, and the resulting state of consciousness will be one of dilemma.† Illusions of movement can therefore be evoked by altering the relative intensity of the stimulus in different parts of the field.

Illusions.

These considerations are made use of by the producers of popular illusions. One such illusion seems especially instructive. The subject is blindfolded and stands on a board of convenient size laid on the floor. One of his hands rests throughout the experiment on the head of an individual standing immediately in front of him. The board is then gradually lifted by four conspirators two or three inches from the floor, while the individual in front gradually lowers himself on to his haunches. The victim now feels as if he were slowly but surely being lifted up to the ceiling, and when told to jump down, having planned a jump of several feet which in reality is only one of two or three inches, his feet find the floor before he expects it, and he falls to the ground. This illusion seems to show that in default of vision the almost complete absence of stimulation of the vestibular organ is not interpreted in consciousness as absence of movement in face of the stream of impulses from the musculo cutaneous field, which so strongly suggest the existence of movement, and are, in fact, so interpreted. The illusion, moreover, can be almost entirely abolished if the onlookers talk. Under these circumstances the blindfolded subject correlates his position in space with the nearness of the voices.

---

† Cf. Sherrington for discussion of degree of potency of stimulus in lower level reflexes.[34]

Ocular vertigo, such as is evoked by looking at a waterfall, &c., is presumably dependent on movements of the eyes and the consequent displacement of the retinal pictures while the body remains stationary. That identical end effects can be produced by such diverse peripheral excitation, as is involved in watching a moving object on the one hand and in passive rotation on the other, appears at first sight remarkable. It finds its explanation, however, in the close interdependence between the oculo motor apparatus and the labyrinth and the close central connexions existing between the two systems, to both there is available a "final common path."

THE OCCURRENCE OF LABYRINTHINE VERTIGO DURING FLIGHT

Can the movements of an aeroplane be rendered sufficiently violent to evoke disturbances of equilibrium such as are evoked in the rotation chair? This question can only satisfactorily be answered by the combination of two experimental methods.

In the first it is necessary to determine the angular acceleration necessary to produce in any individual disturbances of equilibrium, and having done this to determine the angular acceleration possible in an aeroplane. My technical knowledge is far too meagre to permit of my attacking this problem, and the only contribution which I will venture is that no aeroplane can rotate so rapidly and through so small a circle as does the chair when used in the ordinary way for testing vestibular reactions. Another but far less exact method is to observe what happens to oneself in the air. In some observations which I was able to make through the kindness of several flying friends, some of which have already been referred to elsewhere,[35] the following points were revealed. One is bewildered at first by a series of startling sensations which, owing to their novelty, are unintelligible. To look over the side of the machine to see the countryside rising up at one, or to look down only to find the sun are experiences which render accurate observation difficult. Nevertheless in those early days I was never aware of rotatory vertigo, I was merely "lost." When, however, one had learnt to recognise the initial stages of each manœuvre and could therefore anticipate intelligently, the apparent movements of the external world rapidly began to correlate themselves with movements of the machine, and one finally began to look to these apparent movements for information.

The following general conclusions were arrived at: (1) That the power to orientate oneself, except in a "spin," is largely a matter of correctly interpreting the apparent movement of earth, clouds, sea, and sun; (2) that this interpretation is entirely a matter of experience; (3) that it is assisted, to what extent it is impossible to say, by auditory and tactile impressions and by changes in bodily attitude; (4) that during a "spin," provided the gaze is fixed on the ground below (or less preferably on the instrument board), there is no vertigo and no forced movement; (5) that immediately on coming out of a "spin," or even a "loop," "dive," &c., it is possible to identify a momentary disturbance of equilibrium as evidenced by a curious feeling of insecurity and vagueness; and (6) lastly, that vertigo can readily be evoked by keeping the gaze fixed on anything which is moving, or appears to be moving, faster than oneself, such as the wing tip, the tail, or the sun.

These rough observations relate to one individual only and may therefore be constitutional, but their general applicability is supported by the fact that the great majority of pilots (*a*) have learnt without being told to look at the ground when they spin; (*b*) do get giddy if they look at the wing tip or sun; (*c*) are sometimes aware that the termination of any manœuvre involving rotation is the time when they are apt to feel "queer"; and (*d*) do derive much useful information from the apparent movements of the external world.

These considerations lead us to the conclusion that the labyrinthine stimulation produced by evolutions in the air in a majority of healthy young men is not of sufficient intensity to evoke disturbances of equilibrium such as are induced by the rotation chair. This conclusion is corroborated by the practically unanimous statement of the experienced pilots examined that the effects produced by the chair far exceed, and are dissimilar in character to, the effects produced in the air.

Labyrinthine and Ocular Vertigo Contrasted.

On the other hand, a bright sunny day, a clear atmosphere, an aeroplane, and a skilful pilot are the materials par excellence for the production of ocular vertigo. The knock out blow which concusses the labyrinth and "reduces a vigorous athlete to an unstrung bulk of flesh"[36] is not very dissimilar in its effects to sitting in a fast spinning aeroplane facing and watching the tail, for under such conditions one may be reduced to a strictly comparable condition.

In thus suggesting that vertigo of ocular origin is to be expected during aerial acrobatics and vertigo of labyrinthine origin immediately after their termination, we are doing no more than applying the ascertained fact that endolymph movement relative to the canal, and therefore excitation of the crista ampullaris, is non existent during rotation provided the motion is smooth, but at its maximum when rotation is suddenly stopped—i.e., on deceleration of the chair or on coming out of a "spin."

It is evident that were labyrinthine vertigo produced in the air with the same facility as it is in the chair pilots would be helpless in its presence. It is not improbable, as Scott was the first to point out, that the brief period of time when the machine has straightened out from some rotatory evolution is the critical point; at this point, as we have seen, consciousness may be momentarily damped, and in a quick scout machine which goes easily into a spin, a pilot, especially if he is inexperienced, either from lowering of attention or even as a result of actual "forced movement," may throw the machine into a spin in the opposite direction with a fatal result. "Vertigo involves a slight interference with consciousness, since an exact appreciation of the relation of the body to its surroundings is involved in the state called consciousness."[37]

It is well known that stimulation of any of the canals in the horizontal plane is more readily borne than their stimulation in either the frontal or sagittal plane; rapid turning movements of the head are, for example, less disturbing than rapid nodding movements. During a "spin" with the head in the ordinary position and the gaze fixed on the ground the rotation is in the frontal plane, which is parallel to the earth; but when the machine comes out of the spin (i.e., deceleration) and flies on a level keel, supposing the attitude of the head relative to the body remains unaltered, the frontal plane becomes at right angles to the ground and the vertigo, if any, will be experienced in the frontal plane, giving a sensation of falling to right or left. This probably explains the moment of uncertainty above alluded to, and some pilots have discovered for themselves that it is preferable to keep the head down on coming out of a "spin," so that the position of the frontal plane remains unaltered—i.e., parallel to the ground. It is not certain, however, that the benefit derived from looking at the ground is wholly attributable to the accompanying position of the head, and I would suggest that it is partly a device for avoiding *ocular* vertigo. Provided one is two or three thousand feet above the ground, the earth looks homogeneous, there is no sharp detail, and it can therefore easily be fixed with the eye. Now it is well known that vertigo after rotation in the chair can be materially cut short by fixing the gaze.[12] I have, further, recently observed on myself that if a point on the ceiling is fixed through a roll of paper held close to the eye *during* rotation in the chair with the head thrown back 120° the disturbances of equilibrium when rotation is stopped, usually very severe, are very materially diminished.

VARYING TYPES OF REACTION TO LABYRINTHINE EXCITATION

Individuals vary greatly in the intensity of the reaction evoked by excitation of the vestibular system. Some cannot dance, swing, or go on a switchback; some of us are good, some are bad, sailors.

The striking feature of the reaction in such susceptible individuals is its loss of "local sign"; it is not a pure labyrinthine over response (nystagmus, vertigo, forced movements), but rather a replacement of the typical response by another characterised by nausea, vomiting, pallor, collapse, and fall of blood pressure. In these cases, although the peripheral end organ is free from disease, impulses originating in it irradiate widely and overflow with peculiar facility into other systems. Of these systems the motor paths which originate in the nucleus ambiguus are easily the most prominent. This tendency to overflow is a constitutional peculiarity in many normal individuals, who in other directions show no evidences whatever of lack of central control or of inhibition. In others, however, it may occur when the mental and physical health is disturbed from whatever cause. In states of regression it is especially common,[35] and vomiting in the air in a flying officer who had never previously experienced it was in France the signal for his being ordered a rest.

THE "SENSITIVENESS" OF THE LABYRINTH.

On the assumption that a pilot is primarily dependent on the functional efficiency of his vestibular apparatus, it was natural to take steps to discover whether his response to excitation was normal, excessive, or deficient. On admittedly hypothetical grounds a standard response was laid down for aviation candidates in the United States.

After ten turns in 20 seconds with the head 30° forwards, clockwise and counter clockwise, a horizontal nystagmus of between 16 and 36 seconds' duration and one past-pointing with each arm were accepted as normal. Candidates with less than 16 seconds' nystagmus were supposed to be deficient in "motion-sensing acuity," while those with more than 36 seconds were termed "hypersensitive." Out of many thousands of candidates examined only 2·0 per cent. were disqualified on these tests—i.e., about one-fifteenth of all those rejected—the vast majority of rejections being due to errors of vision.[38]

The average duration of nystagmus of all the candidates examined was 23·5 seconds after turning to the right and 23·2 seconds after turning to the left. Of those who showed less than 16 seconds' after-nystagmus, the average duration was 12·4 seconds both to right and left; of those who showed more than 36 seconds the average was 50·2 seconds after turning to the right and 48·0 seconds after turning to the left. The average number of past-pointings of all candidates was with the right arm after turning to the right and left 3·9, with the left arm 3·8.

The view that these simple tests are capable of indicating the functional integrity or otherwise of a portion of the vestibulo-cerebello-cerebral system is disputed by no one, nor can the arbitrary setting of the standards laid down be condemned from the point of view of practical policy. Whether, however, we are justified in asserting that an individual with less than 16 seconds' after-nystagmus is deficient in labyrinthine sensitivity, or that one with more than 36 seconds is the possessor of a hypersensitive labyrinth, is an entirely different proposition. It has, in fact, been shown that war pilots in the summer of their flying careers may exhibit reactions far in excess of the average.[10] As has already been pointed out, to test the degree of sensitivity of an organ by employing a stimulus far in excess of what is physiological is a curious method of procedure, but to draw far-reaching deductions therefrom is frankly unscientific. "The only scientific way of comparing degrees of sensitiveness of the vestibulo-cerebellar system is to obtain the minimal angular acceleration necessary to produce consciousness of rotation, or the minimal angle of tilt recognisable in consciousness." (Scott.)

It was hoped at one time by the employment of these tests to eliminate those individuals whose response to labyrinthine excitation was of the "vagus variety." It was thought that the individual who was prone to sea-sickness and disliked dancing and swinging would be likely to suffer from nausea and sickness in the air. Our expectations in this direction were not completely fulfilled. In response to the "chair" tests there was observed a frequent lack of correlation between the subjective and objective effects; an individual, for example, might show very slight forced movements and a short nystagmus period and yet suffer intense giddiness, with nausea, vomiting, and circulatory collapse. As a matter of experience, I have not yet met a pilot who is sick in the air and is a good sailor, but I know of hundreds who have never felt sick in the air who always have been, and no doubt still are, atrocious sailors. Hence a history of sea-sickness in assessing a candidate's suitability for flying must be viewed dispassionately. It would seem that the specific character of the stimulus, to estimate which our present methods are inadequate, plays a part. How else can we explain a case such as the following?

Captain Z., M.C., a dreadful sailor, waltzing makes him sick and swinging makes him giddy; nevertheless, he can throw a fast scout machine about in the air without the slightest hesitation or discomfort, and was twice decorated for successful gallantry in combats with enemy machines. After turning in the chair his nystagmus period was 18 seconds to the right and left, he showed violent forced movements, but experienced no visceral discomfort whatever.

To summarise, therefore, it is admitted that the rotation tests satisfactorily demonstrate the functional integrity of the vestibular system and its central connexions. Further, they may be useful in revealing not a vestibular system which over-responds, but rather a central nervous system in which impulses originating in the labyrinth are imperfectly controlled; but imperfect control in the chair is not necessarily associated with imperfect control in the air.

SUMMARY.

I have attempted to indicate that the art of flying, as regards the sensory-motor coördination involved, is an art which may be acquired by any healthy individual like other accomplishments, such as playing games or playing the organ, and that the ability to fly depends primarily on the wonderful adaptability of the human organism. This adaptability, again, is the immediate result of the ability of man to project his powers of appreciation and to benefit by experience. Just as it is impossible to gauge in mathematical terms the extent to which the various afferent and efferent systems participate in securing the perfect harmony necessary for carrying out the intricate evolutions of everyday life, so is it both unprofitable and unsound to indulge in similar speculations in regard to the art of flying. We must rest content in the knowledge that the human machine is so perfected as to permit of its carrying out the necessary coördinations. It would, moreover, be a grave mistake to suppose that the function subserved by any organ or group of organs has a significance under the artificial conditions of flight other than that which it has in life on the ground. Such a distinction has, however, been advanced in the case of the vestibular system, and it is therefore necessary to have a clear conception of its functions under natural conditions.

The conception of the labyrinth advocated by Cyon as the peripheral organ of the sense of space has never found acceptance with the main body of physiological opinion; it fails, moreover, to stand the test of experiment in the air. Moreover, it is highly improbable that an organ so peculiarly adapted by its anatomical structure to respond to stimuli arising exclusively within the body should be capable of subserving so projected an aspect of sensation as is involved by the term "the sense of space." On the other hand, anatomy and physiology combine in demonstrating that the labyrinth can and does appreciate movements in the three planes of space. In man and the higher vertebrates generally the only part of the body which is capable of movement in three planes is the head, and it is reasonable to conclude that the labyrinth is affected essentially by head movements, whether such movements be confined to the head or be part of a total movement of the individual. The range of these movements is strictly limited, of the head alone by the structure of the vertebral and occipito-atlantal joints, and of the body as a whole by its general structure and its ordinary physiological activities.[‡] The speed and range of these movements may, however, be artificially increased, and the excitation of the labyrinth thereby evoked will be correspondingly greater. The whirling dancer induces as severe an excitation of his semicircular canals as does Barany's chair, and with the same results except that by practice he has learnt to antagonise the effects of the reaction. That he is paid to whirl is surely evidence that his activities border on the unnatural. The point, however, to be insisted on is that rapid and continuous rotation in man can only be effected artificially, and that however produced it constitutes a violent stimulus and evokes a violent response.

The labyrinth, then, appreciates and so helps to modify and control the movements, and also the position, of the head, and, since the head is the leading segment, as a secondary effect it modifies and controls the movements and attitude of the rest of the body. Further, in the head end of the animal are placed the great distance-receptors, the eyes, "set movably in the head,"[36] and it is by reason of its ability to recognise movements of the head that the labyrinth is able reflexly to effect corresponding movements of the eyes. "The control of the oculo-motor muscles lies largely with the labyrinth."[36]

The function of the visual apparatus as a means of projecting his sensations into the environment has been developed in man to its culminating point, and it cannot be a matter for surprise that receptors subserving sensations with little, if any, projected quality come to be subordinate, so to speak, to those in which this quality is more in evidence. Impulses originating in the labyrinth reach, but hardly pass, the threshold of consciousness, or at least we cannot identify their individual presence as we can those of sight, sound, &c.; they are merely a wave in the great sea of impressions which together make up the state of consciousness. In this light they must be studied, not in isolation but in coöperation. It is especially through the close coöperation of the labyrinth, the proprio-ceptor of the head,[39] with the visual apparatus, the great distance receptor of the head, that the functions of the labyrinth derive so much of their importance in human physiology

---

[‡] By this I intend a comparison between the ordinary physical activities of man as opposed to those of the Japanese spinning mouse or tumbler-pigeon.

"The function of the labyrinth is to keep the world right side up for the organism by keeping the organism right side up for the world"[38] This statement is peculiarly apposite in the case of those who explore the air, since it is by reason of the pre eminent influence of visual sensations and the necessity for their accurate adjustment that the labyrinth gains its true significance for the pilot We can, therefore, rest content in the knowledge that our conceptions of labyrinthine activity during flight harmonise with those broad conceptions of the activities of the nervous system in general, and of the labyrinth in particular, which science owes to the brilliant researches of Sherrington and his even more brilliant interpretations

CONCLUSION

In these lectures an attempt has been made to portray the mental and bodily mechanisms by which the healthy organism strives with varying success to counteract the abnormalities of its surroundings. It is difficult to avoid the conviction that were we to adopt a somewhat similar attitude in studying the functional reactions of the organism to abnormal processes arising not from without but from within itself—viz, the processes of disease—we should realise more than we do now that some at least of these reactions are not merely consequential and nocuous but rather compensatory and beneficial It would, further, appear that some such attitude is likely to foster a closer working alliance between the science of medicine and the more exact sciences on which it is founded, an essential preliminary to the advancement of medical thought and consequently of medical practice.

RESEARCHES ON THE TREATMENT OF BENIGN TERTIAN FEVER.

BY HUGH W ACTON, M R C S, L R C P LOND,

MAJOR I M S I/C MALARIAL RESEARCH LABORATORY, BRITISH MALARIAL DEPÔT, *DAGSHAI, SIMLA HILLS*

THE results obtained with the help of my co workers, Dr Dagmar Curjel, W M S, and Assistant Surgeon J. O. Dewey, I M D, whilst I was in charge of the Malarial Research Laboratory, Dagshai, appear to me likely to lead to important advances in the treatment of these fevers Hitherto the treatment of malaria was summed up in one word, "quinine," and the only points at dispute were *the methods of administration* and the length of time this alkaloid should be taken The other alkaloids of cinchona bark have been used by numerous observers, but as far as I am aware have never been accurately tested MacGilchrist (1915), who made the most systematic trial hitherto recorded of these alkaloids, was unfortunate in having to test them under conditions where reinfections could not be excluded and where the cases could not be observed sufficiently long to exclude all the relapses The universal belief that quinine is equally a specific for all types of malarial fever will have to be abandoned before any material advance can be made in the treatment of these fevers. Malarial fever should be regarded not as one disease, but a group of three different fevers, due, as is already known, to three distinct parasites, and two at least of these require different alkaloids of cinchona bark for their treatment After making such a dogmatic statement, I will first explain how quinine came to be regarded as a specific for all three types of malarial fever.

Quinine invariably exerts an immediate effect on all three types of malarial infection, causing a rapid amelioration in symptoms and disappearance of the asexual parasites from the peripheral blood The annihilation of every asexual parasite in the body, or the prevention of relapses, is, however, the only test by which one can truly estimate the specific action of these alkaloids From the present statistical evidence it is almost impossible to estimate the degree to which this complete cure or sterilisation has been attained, as the figures are markedly influenced by one or more of the following factors —

(1) In the tropics quinine has to be administered under unfavourable circumstances—viz, under epidemic conditions—and reinfections may occur as soon as the quinine is withheld This effect may give rise to too unfavourable an impression as regards the cure rate

(2) Cases are often not observed much longer than the duration of treatment Many of the relapses are not seen by the same medical officer, and in this way too favourable a clinical impression is created as regards the curative value

(3) The microscope is not sufficiently employed Fevers are often diagnosed as "malaria" from symptoms only, and malignant tertian infections from the presence of pernicious symptoms

In spite of these factors, which may cause an unduly favourable or unfavourable estimate of the sterilisation rate, there is a general clinical impression that these three fevers relapse after quinine treatment, in the following order of frequency quartans most frequently, then benign tertians, and malignant tertians least frequently of all This corresponds to our own experience, that the cure rate produced by quinine in the three types of fever is as follows 90 per cent or over in malignant tertians, 20 to 30 per cent in benign tertians, and under 20 per cent in quartan infections

The Test of a Cure.

Many of the previous workers on the action of the cinchona alkaloids were compelled to work under unfavourable conditions Stephens and his co workers had to a large extent laid down the conditions that were necessary for the test of a cure We were more fortunate in treating British troops under our immediate command, where every detail could be followed in the treatment. Every one of our recorded cases remained for two months or longer under observation after completion of treatment The adverse factors already mentioned did not affect our figures, as they could be prevented by—

(1) The exclusion of reinfections amongst our cases during treatment and observation Dagshai is situated on

an isolated hill-top at 6000 feet above sea-level; there are very few sites suitable for breeding-places for the anophelines, and the temperature conditions are, for the greater part of the year, unfavourable for the fertilisation of the female gamete.

(2) Every case recorded as a cure was observed for at least two months, sometimes longer. This observation time-limit, first suggested by Stephens, was tested by plotting every parasitic relapse that occurred amongst our benign tertian cases. These relapses numbered 978, and are shown in the following table.

Table I. shows the frequency distribution of 978 parasitic relapses, all due to the benign tertian parasite, which occurred during and after treatment, and are shown in intervals of weeks.

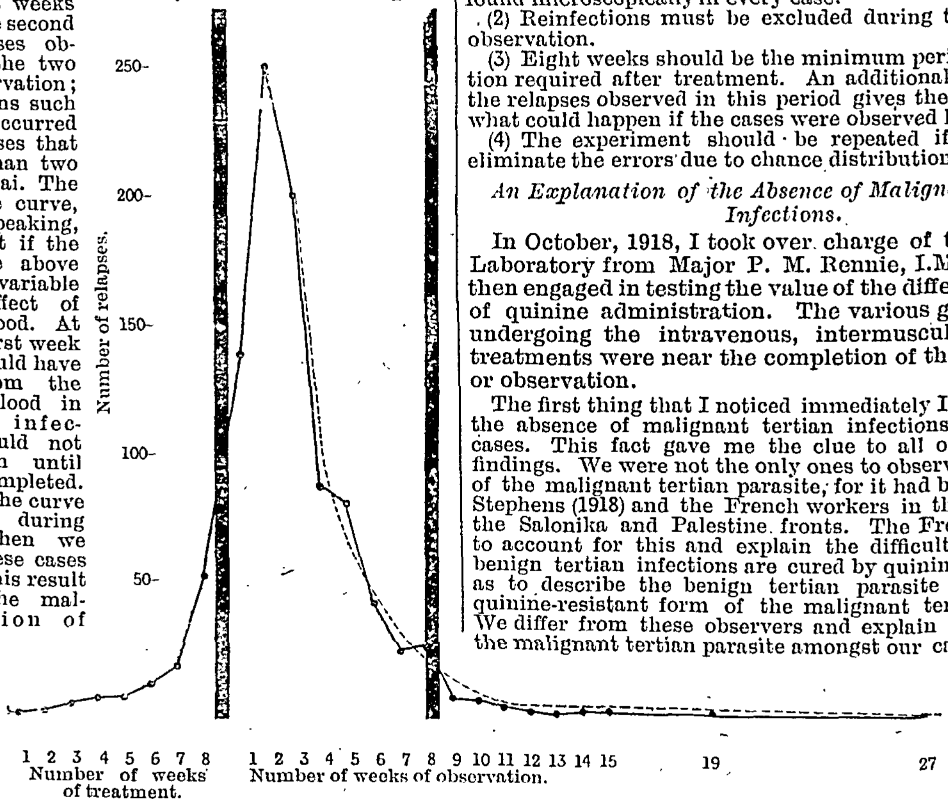
TABLE I.

(A) Interval of weeks. (B) Number of relapses.

—	During treatment.								After treatment.																	Total.
(A)	1	2	3	4	5	6	7	8	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	19	27	—
(B)	—	1	4	6	7	12	19	53	139	248	199	89	82	43	25	26	7	6	4	2	1	2	1	1	1	978

These results are better depicted in the form of a graph, which is here shown. The two vertical bars divide the curve into three parts. The first part contains the relapses observed during the eight weeks of treatment; the second part the relapses observed during the two months of observation; the third contains such relapses as occurred amongst the cases that stayed longer than two months in Dagshai. The first part of the curve, theoretically speaking, should be absent if the statement made above about the invariable immediate effect of quinine holds good. At the end of the first week all parasites should have disappeared from the peripheral blood in benign tertian infections, and should not be seen again until treatment is completed. Instead of this the curve gradually rises during treatment. When we investigated these cases we found that this result was due to the maladministration of quinine, by patients avoiding treatment, intermittent types of treatment, and too large doses. As soon as these factors were recognised and corrected no further parasitic relapse occurred during treatment.

Graph showing Frequency Distribution of 978 Parasitic Relapses.



The second part of the curve shows the time frequency of the relapses that occur during the two months' observation after treatment. As the first part of the curve is due to an error it is not included in the calculation of the mean and standard deviation. The mean of these figures is at 3·404 weeks, and the standard deviation is ± 2·42 weeks, indicating that three-quarters of the relapses occur between the first and sixth week after treatment. The eight weeks' period of observation after treatment laid down by Stephens is a sound practical period to test a cure, as it includes over 90 per cent. of the relapses that may occur after treatment. The third part of the curve from the ninth week onwards could not be accurately determined by us, as we could not keep the men indefinitely away from their units during war. I consulted Professor Karl Pearson, F.R.S., to see if he could help me to obtain some idea at which point this curve might possibly end. I must thank him for the trouble he has taken to work out the figures. He tested them by two different methods and found that the end-point occurs somewhere about the thirty-sixth week—that is, in benign tertian infections, if the blood is examined every week for nine months and no parasites are found, the case can be regarded as an absolute cure. A rough estimate of this portion of the curve can be arrived at by drawing a free-hand curve from the point at three weeks to the thirty-sixth week, shown as a dotted line in the graph. This portion represents another 6 per cent. of relapses on those already observed during the eight weeks of observation. This additional 6 per cent. gives the necessary correction to obtain the total number of relapses that would occur if the cases were observed for the full nine months after treatment.

(3) The parasite was seen microscopically in every case before the patient was placed on treatment. Individuals harbouring the same species of malarial parasites were tested together under the same conditions. In much of the older work the three species of parasites were indiscriminately mixed up in the same treatment groups.

Stephens (1918) suggested that a seasonal influence was present in his cases, which appeared materially to affect the cure-rate. In an article now in press we have dealt with this point, and consider that the error of chance distribution could explain the variations in cure-percentage better than any seasonal influence. It is immaterial which explanation is correct, but we know that such fluctuations do occur, and a repetition of the test would settle the question whether a cure-percentage was accurate or not.

The conditions required to test a particular cure for malarial fevers may be summed up briefly—

(1) The population under investigation should be sufficiently large and homogeneous. At least 100 men should be treated, and the parasites must be of the same species and found microscopically in every case.

(2) Reinfections must be excluded during treatment and observation.

(3) Eight weeks should be the minimum period of observation required after treatment. An additional 6 per cent. on the relapses observed in this period gives the correction for what could happen if the cases were observed longer.

(4) The experiment should be repeated if necessary to eliminate the errors due to chance distribution.

An Explanation of the Absence of Malignant Tertian Infections.

In October, 1918, I took over charge of the Research Laboratory from Major P. M. Rennie, I.M.S., who was then engaged in testing the value of the different methods of quinine administration. The various groups of men undergoing the intravenous, intermuscular, and oral treatments were near the completion of their treatment or observation.

The first thing that I noticed immediately I took over was the absence of malignant tertian infections amongst our cases. This fact gave me the clue to all our subsequent findings. We were not the only ones to observe this absence of the malignant tertian parasite, for it had been noticed by Stephens (1918) and the French workers in their cases from the Salonika and Palestine fronts. The French, in order to account for this and explain the difficulty with which benign tertian infections are cured by quinine, went so far as to describe the benign tertian parasite as an altered quinine-resistant form of the malignant tertian parasite. We differ from these observers and explain the absence of the malignant tertian parasite amongst our cases as due to the specific action of quinine, for all our cases had undergone a course of treatment with this alkaloid before arrival at the depôt. This statement is based on the following data.

(1) Out of 992 parasitic findings only 14 individuals were found to harbour the malignant tertian parasite. There were 978 showing benign tertian infection.

(2) At this depôt our experience of malignant tertian infections was small, but every case treated by quinine was cured. This corresponds with the experience of Thomson (1917) and Barlow (1915). Thomson estimates the cure-rate at 80 per cent. and Barlow at 100 per cent. if treatment were continued for a month.

(3) Our cases were drawn largely from the Punjab, a province where there is a seasonal prevalence of these two parasites, benign tertians at the beginning and malignant tertians at the end of the hot weather. In spite of this seasonal prevalence the malignant tertian parasite was rarely found, as all our cases had been treated with quinine before arrival at the depôt.

(4) One hundred and two men had been diagnosed as malignant tertian infections, crescents being noted in their

medical history sheets. These men had been treated with quinine at their units in the plains. In Dagshai they only received an iron tonic. There were no malignant tertian relapses, 64 relapsed with benign tertian infection, and 38 did not relapse. This preponderance of benign tertian relapses in a malignant tertian series is probably due to double infections, as it is difficult to see how the pathologists could have made an error in diagnosing crescents.

(5) In a similar series of 102 different men diagnosed as benign tertian infections these parasites were noted in their medical history sheets, and the men were treated exactly as the group above. There were 76 benign tertian relapses, no malignant tertians, and 26 did not relapse. The lower cure rate in benign tertian infections should be noted and the absence of malignant tertian relapses in both series.

The specific action of quinine on the malignant tertian parasite explains how this parasite disappears from the blood of malarial patients who have returned home from the tropics, as such individuals have been well drugged with quinine.

The Low Sterilisation rate of Quinine in Benign Tertian Infections

The second important point that became apparent after we analysed our results was the low cure rate of quinine in benign tertian infections. Out of 663 cases of this infection treated with quinine there were 32.4 per cent of cures; nearly 70 per cent of the cases relapsed in spite of treatment. The series of cases given in Table II. were commenced in Major Rennie's time and completed by us. The results obtained were as follows.

Table II. gives a comparison of the results we obtained by the different methods of quinine administration in benign tertian infections.

TABLE II.

Method	No of cases	Cure per cent	Duration of treatment	Quinine in grains per course
(A) Intravenous combined with oral	100	18	4 days to 8 weeks	48 to 678
(B) Intermuscular combined with oral	94	27.6	8 weeks	1284
(C) Oral alone—				
(1) Stephens intermittent 45 gr per diem for two consecutive days weekly	90	18.8	8 „	720
(2) Stephens intermittent 30 gr per diem for two consecutive days weekly	113	30.0	8 „	480
(3) Ross and Thomson's method continuous for four months	76	52.6	16 „	1980
(4) Continuous for ten days 30 gr per diem	190	42.1	10 days	300

Comments

(1) The duration of the treatment is an important factor in the cure. Rennie found that both in the intravenous (1 to 5 injections) and intermuscular (12 injections) groups the injections had to be followed by an oral treatment lasting in all two months, in order to obtain a better apparent percentage. In the long continuous treatment (Ross and Thomson), extending over a period of four months, the cure percentage worked out at 52.6, or double that of the two months' courses.

(2) The method of quinine administration did not materially affect the cure rate. The intravenous method gave the best immediate results and caused the parasites to disappear from the peripheral blood quicker than the other methods. The absolute cure rate was bad, as the first few cases were only given 2 to 5 injections, which were not followed by quinine orally.

(3) The cure percentage was low in all the courses of two months, and varied from 18 to 30 per cent. The short continuous course of ten days gave a higher cure percentage than was expected—i.e., 42.1 per cent. It is possible that the error of chance distribution made this figure unduly high, but it must be noted that another rather serious and unknown error was introduced into the group by the fact that some men bought quinine during the period of observation and administered it to themselves. The latter factor only affected this group in one series, as the armistice had been declared and the men were anxious to return to their units in the hope of getting home quicker.

We are therefore able to confirm the fact that quinine has a low rate of cure in benign tertian infections. This has already been shown by numerous other observers.

The Cause of the Preponderance of Benign Tertians Amongst our Cases.

The malarial population we investigated at Dagshai was a selected one. This selection was brought about by quinine, as all our cases had received a course of this drug before arrival at the depôt.

We have already stated that quinine exerts a highly specific action on the malignant tertian parasite, and therefore practically eliminates this parasite from the cases which have undergone a good course of treatment. The cure rate of quinine for benign tertians is low, and under such conditions quartan and benign tertian infections will relapse owing to the failure of quinine and appear again and again amongst a treated population. Quartans form a very small proportion of the cases (this infection is relatively rare in the Punjab) and can be neglected. The infection seen amongst a treated population in a non-infected area is practically all due to the benign tertian parasite.

The Effect of Repeated Courses of Quinine on Benign Tertian Infections.

After I had analysed our Dagshai results and seen the low cure rate of quinine in benign tertian infections, I considered that by giving short courses of treatment a larger number of effective men could be obtained in a shorter space of time than by giving the long courses of four months quinine treatment advocated by Ross and Thomson. The results of this experiment are shown in Table III.

This group consisted of 475 men who had been treated by quinine for malaria and sent up to Dagshai, where they were placed on an iron tonic. Out of these, 277 relapsed, and benign tertian parasites were found in every one of these relapses. Out of these 277, 204 could be observed for the full two months after a further course of treatment, and of these 145 relapsed. Ninety-five could be followed for the full period after the second course of treatment at Dagshai, and 76 relapsed; 45 of these could be followed after the third course and 32 relapsed. Ten of the 32 relapses could be followed after the fourth course, and 8 relapsed. The actual cure rates for these four courses at Dagshai work out at 28.9 per cent., 20 per cent., 28.28 per cent., and 20 per cent. respectively, or an average of 24.4 per cent. for each course of treatment. The maintenance of the cure rate about a constant of 25 per cent. from the first to the fourth course of treatment is a very important fact, as it indicates that neither does the parasite become more and more quinine resistant, nor does the host's resistance alter, otherwise the cure percentage should diminish with each subsequent course. Clinically one cannot say whether a given case will be cured with one or many courses; it seems immaterial whether the patient is undergoing his first or fourth course, for with each course he stands an equal chance of cure.

Whatever explanation may later on be advanced to account for this result, it shows that the cure rate is dependent on some chance factor.

The Rate of Parasitic Destruction.

We know that the asexual malignant tertian parasite forms 8 to 12 merozoites every 48 hours and is most influenced by quinine. The asexual benign tertian parasite forms 16 to 24 merozoites every 48 hours and is less easily destroyed by quinine. On the other hand, the quartan parasite has the slowest rate of multiplication, 8 to 12 merozoites every 72 hours, and is the most refractory to quinine. This difference in the multiplication-rate is thus not sufficient to explain the difference in cure-rates by quinine, although it undoubtedly plays a part.

In our calculations, if we disregard the occurrence of deaths and the production of gametocytes (i.e., non-multiplying forms), we can consider the rate of multiplication to be a continuous one—that is, 12-fold in malignant tertian and 24-fold in benign tertian infections every three days. An adult man of 68 kg. body weight possesses about 25,000 billion erythrocytes. Ross, in his enumerative studies, found that in severe infections about 12 per cent. of the erythrocytes were infected with parasites (3000 billion parasites), and when the parasites fell below 250 million (1 parasite in 100,000 erythrocytes) they produced little or no symptoms. Theoretically, a single parasite would be capable in three weeks' time of multiplying sufficiently to produce fever. Every parasite in the body must be destroyed before a complete cure or sterilisation is effected. In latent malaria we know that a large number of parasites can exist in the host and multiply without causing obvious symptoms, but any condition that depresses the vitality of the host can convert the latent malaria into an active disease. As regards the rate of parasitic destruction, we know that a single dose of quinine cannot cure a case of malignant tertian infection, but a series of doses are required extending over a month before a complete cure results. This fact points to the conclusion that the rate of parasitic destruction must be under 100 per cent., otherwise a few intravenous injections of quinine would be sufficient to sterilise every case of this infection. The rate of destruction must be over 95 per cent., otherwise the course of treatment would have to be prolonged for more than a month. Theoretically the rate of parasitic destruction by quinine in malignant tertian infections is about 98 per cent. of each asexual brood. In benign tertian infections, even after a four months' course of quinine treatment (Ross and Thomson), only 50 per cent. of the cases are sterilised.

Quinine in all types of malarial fevers causes an immediate effect on symptoms and a rapid disappearance of parasites from the peripheral blood. Ross considers that this effect is largely due to a reduction in the parasitic population from 3000 billion or more (febrile stage) to 250 million (afebrile). Under these conditions the rate of destruction in benign tertian infections must lie between these two values, 90 and 98 per cent., and the difficulty in sterilisation shows that the rate must be nearer 95 per cent. than 98 per cent.

The cure-rate for a month's course of treatment in this infection varies for the different alkaloids as follows: Quinine 20 per cent., cinchonine about 40 per cent., cinchona febrifuge 50 per cent., cinchonidine and quinidine about 60 per cent.; so that the last two alkaloids must cause a greater percentage destruction of each generation. As the rate of multiplication of the benign tertian parasite is about twice that of the malignant tertian, it follows that in order to destroy every parasite in the body of the host the treatment should extend over six weeks, instead of a month, as for malignant tertian infections.

The Effect of the Total Alkaloids of Cinchona Bark on Benign Tertian Infections.

Cinchona febrifuge is a preparation containing the total alkaloids extracted from cinchona bark, made at the Government factories in India and issued in the form of 3½ gr. tablets. According to MacGilchrist, its average composition is as follows:—

		Per cent.
Crystallisable alkaloids	Cinchonine...	18·58
	Cinchonidine	5·84
	Quinine	7·40
	Quinidine	22·83
Non-crystallisable alkaloids ...	"Quinoidine"	29·12
Moisture, ash, &c.		16·23

The bark, in addition to these alkaloids, contains acids, neutral principles, colouring matter, a trace of volatile oils, gum, starch, and other vegetable matter. The large amount of ash present in cinchona febrifuge is due to the fact that magnesium sulphate is added to the alkaloidal mass to facilitate the preparation of tablets. Cinchona febrifuge was advocated many years ago by Prain owing to its cheapness. We determined to give it a trial, for if it proved to be as efficacious as quinine, its general use would effect a considerable saving in the amount of bark now used to extract quinine. The drug was tested on two series of men. The first series of 53 men were treated for 21 days, with 21 grains given daily by the mouth, the cure-percentage worked out at 50·9. The second series of 57 men were treated as above, but the cinchona febrifuge was only given for 10 days; the cure-percentage worked out at 52·7. Combining these two groups of men (110 individuals) the cure-percentage works out at 51·8. The conclusions we arrived at were as follows:—

(i.) The administration of cinchona febrifuge in benign tertian infections is better than quinine. A three weeks' course gives about the same curative results as a four months' course of quinine (Ross and Thomson's method). The immediate results are also slightly better.

(ii.) The amount of cinchona febrifuge given during a course amounts to 441 gr. and costs 1*s.* 1*d.*, as compared with 1980 gr. of quinine for a four months' course, costing 16*s.* 8*d.* (price in June, 1919).

(iii.) Cinchona febrifuge given in tablet form is more pleasant to take and less toxic than quinine.

(iv.) A considerable saving would be effected in the amount of bark, as the same quantity of bark which yields from 5 to 7 lb. of quinine would give 100 lb. of total alkaloid. This is an important consideration at the present time, when there is a shortage of quinine.

The benign tertian parasite is responsible for about 50 per cent. of the malarial infections in India, and in England, amongst the troops returned from the tropics, it is practically the only malarial infection seen. The employment of cinchona febrifuge in this infection would save the Indian Government approximately 2½ lakhs, or £22,500, annually in drugs, excluding the question of efficiency in men. This result alone should justify the value and need of further research work in the treatment of these malarial fevers.

The Effect of the Cinchona Alkaloids on Benign Tertian Infections.

Fourteen alkaloids have been isolated from the various species of cinchona bark, since Pelletier and Dumas in 1820 first discovered quinine and cinchonine. The names and formulæ of the various alkaloids found in cinchona bark are as follows:—

(A) Crystallisable alkaloids.

Cinchonine and its isomeride. $C_{19}H_{22}ON_2$—Cinchonine and cinchonidine.
Dihydrocinchonines $C_{19}H_{24}ON_2$—Hydrocinchonine, hydrocinchonidine.
Methoxycinchonines $C_{20}H_{24}O_2N_2$—Quinine, quinidine.
Methoxydihydrocinchonines $C_{20}H_{26}O_2N_2$—Hydroquinine and hydroquinidine.
Alkaloids of the formula $C_{19}H_{24}O_2N_2$—Quinamine and conquinamine.
Alkaloids of the formula $C_{16}H_{18}ON_2\frac{1}{2}H_2O$—Paricine.
Alkaloid of unknown composition—Javanine.

(B) Amorphous alkaloids known as "quinoidine."

Dicinchonine $C_{38}H_{44}O_2N_4$.
Diconquinine $C_{40}H_{46}O_4N_4$.

We can dismiss the amorphous alkaloids from a therapeutic point of view, for we treated a dozen cases with the Laverain remedy (a mixture of quinoidine, arsenic, and picric acid). All these cases relapsed, and some of them had parasites in the peripheral blood during the whole course of treatment. Eight only of the above crystalline alkaloids need be considered, as the others exist merely in minute quantities. These alkaloids can be grouped in two series.

(A) The cinchonine series, which includes cinchonine and its isomeride cinchonidine; and the dihydrocinchonines—hydrocinchonine and hydrocinchonidine.

(B) The quinine or methoxycinchonine series, including quinine and its isomeride quinidine, hydroquinine and its isomeride hydroquinidine.

We can dismiss quinine at once, as only 7·4 per cent. of this alkaloid is present in cinchona febrifuge, and we have seen that this alkaloid produces a low cure rate in benign tertian infections. Cinchonine was tested in 14 patients, of whom eight relapsed. The drug is very toxic and badly tolerated. I had the greatest difficulty in persuading these individuals to continue their treatment for the full three weeks, owing to the intense symptoms of cinchonism. The number of relapses did not justify the employment of this toxic alkaloid for any further trials. The hydro-alkaloids of the quinine and cinchonine series I was unable to obtain, and we were therefore left to test the two alkaloids, quinidine and cinchonidine.

I placed a batch of men on treatment with these two alkaloids. At this important stage of my research I was ordered to the recent Afghan affray. The testing of these alkaloids I therefore entrusted to my co-worker, Assistant-Surgeon Dewey, who has kindly forwarded to me the results obtained.

Quinidine sulphate 10 gr. orally twice a day for 21 days; 62 cases of benign tertian infection treated, of whom 23 relapsed. Cure-percentage 62·9 per cent.

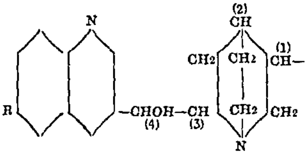
Cinchonidine sulphate 10 gr. orally twice a day for 21 days. Forty-six cases of benign tertian infection treated, of whom

17 relapsed, cure percentage, 63 1 per cent As cinchona febrifuge contains 22 8 per cent of quinidine and 5 84 per cent of cinchonidine, the efficacy of the total alkaloids is dependent largely upon the quinidine content or the cinchonidine quinidine mixture An interesting point is that many have unknowingly used quinidine, for Messrs Howard, of Ilford, informed me that the bulk of the quinidine they extract is sold for the Eastern market, where, no doubt on account of its cheapness, it is substituted for quinine

This result of the value of quinidine and cinchonidine at first appeared rather puzzling to me, as my knowledge of the stereo isomerism of these alkaloids was very limited, and I am deeply grateful to Mr H King, M Sc , of the Medical Research Council's scientific staff, for all the help he has given me on the chemical aspect of this problem

The Stereo isomerism of the Cinchona Alkaloids

The researches of Konigs, Skraup, and Rabe have led to the assignment of the following general formula being assigned to these cinchona alkaloids —



Where R = H in the cinchonine series,
= OCH_3 in the quinine series
R = CH CH_2 in the non hydro-alkaloids,
CH_2 CH_3 in the hydro-alkaloids

The alkaloidal molecule consists of two portions—the quinoline nucleus on the left, and the quinuclidine nucleus, more commonly spoken of as the "second half" These two portions are connected by a secondary alcohol group (CHOH) The position of the four asymmetrical carbon atoms are shown, numbered (1) to (4) Each substance of the above formula should therefore have 16 optically active isomerides, 8 of which would of necessity be the enantiomorphous (mirror image) forms of the other 8 The number of those actually known is very small, as the following considerations show The asymmetry of the carbon atoms (1) and (2) is the same for the four alkaloids, cinchonine, cinchonidine, quinine and quinidine, as on oxidation they all yield the same dextrorotatory compound—meroquinene—in which substance the asymmetry of the carbon atoms at (3) and (4) is destroyed In agreement with this observation is the fact that β vinyl α quinuclidine oxime is the same when formed from any of these four alkaloids A loss of asymmetry of the carbon atom at (4) occurs when these four alkaloids are reduced to dioxy bases, as the secondary alcohol group (CHOH) is replaced by $—CH_2—$

In spite of this loss of asymmetry four different dioxy basis are formed—viz , cinchotenine, cinchotenidine, quitenine and quitenidine It follows that the different optical activity of these bases and the four alkaloids is conditioned by the asymmetry of the carbon atom (3) This is further supported by the observation that quinine and quinidine both yield the same dextrorotatory quinotoxin, whilst cinchonine and cinchonidine yield the same dextrorotatory cinchotoxin In this case the asymmetry of both carbon atoms at (3) and (4) is destroyed At present it is not known what part the carbon atom at (4) plays in the optical activity of these alkaloids

The cinchona alkaloids may therefore be bracketed together in pairs as follows —

Cinchonine—cinchonidine Hydrocinchonine—hydrocinchonidine
Quinine—quinidine Hydroquinine—hydroquinidine

The chemical differences between these four groups are as follows The quinine series are methoxycinchonines—i e , alkaloids in which H of the cinchonine series has been replaced by a CH_3O group at position 6 in the quinoline ring The hydro alkaloids differ from the non hydro alkaloids in that the vinyl group (CH CH_2) of the latter has been converted into a CH_2 CH_3 group The difference between the members of each pair—e g cinchonine and cinchonidine —is due solely to the spatial arrangements of the atoms around the asymmetrical carbon atoms at (3) and (4)

The following table shows the magnitude and signs of the optical activity of the above alkaloids, as base in alcohol as a solvent

Alkaloid	Hydro-alkaloid	Isomeride	Hydro-isomeride
Cinchonine $[\alpha]_D + 224\ 4$	Hydrocinchonine $[\alpha]_D + 189\ 8$	Cinchonidine $[\alpha]_D - 111$	Hydrocinchonidine $[\alpha]_D - 98\ 4$
Quinine $[\alpha]_D - 158\ 2$	Hydroquinine $[\alpha]_D - 142\ 2$	Quinidine $[\alpha]_D + 215\ 5$	Hydroquinidine $[\alpha]_D + 265\ 3$

Now all of the above crystalline alkaloids which have been tested exert a marked effect on the symptoms, and disappearance of the parasites from the peripheral blood in cases of benign tertian infection, and those I have tested have the same action on the malignant tertian Again, my co worker, Dr Dagmar Curjel, tested the effects of these alkaloids on the hæmoproteus of the pigeon, and found that they had no parasiticidal action These alkaloids, therefore, show a marked selection for the human malarial parasite, but in different degrees We have already seen that quinine is a specific for the malignant tertian parasite, and MacGilchrist (1915) considered that hydroquinine was even better than quinine Our Dagshai results show that quinidine and cinchonidine are more selective for the benign tertian parasite than quinine or cinchonine

The Factors on which the Parasiticidal Action Depends.

As far as can be reasoned from a chemical study, the parasiticidal action of these cinchona alkaloids is dependent on three factors in the complex alkaloidal molecule

(i) The group occupying position 6 in the quinoline ring Cinchonine is very toxic for man but the substitution of a methoxy group (CH_3O) in the quinine series decreases the toxicity without materially altering the parasiticidal action Grimaux and Arnaud have shown that toxicity increases with further increase in the size of the radicle occupying this position

(ii) The vinyl group (CH CH_2) in the quinuclidine system The vinyl group is replaced by a carboxylic group (COOH) in the formation of quitenine and cinchotenine, and Ramsden has found quitenine inert against the malarial parasite The inactivity may be due to a chemical reaction between an acid and the alkalies of the plasma The vinyl group is not a decisive factor, as it is present in cinchotoxin and quinotoxin, and both these keto bases have no parasiticidal action against the malarial parasite The hydrogenation of the vinyl group (CH CH_2) to CH_2 CH_3 in the hydro alkaloids renders such alkaloids more difficult to oxidise, and they are accordingly not easily broken down in the body tissues This may increase their parasiticidal action MacGilchrist has shown that hydroquinine has a more potent action than quinine on the malignant tertian parasite

(iii) The grouping of the quinuclidine system around the asymmetrical carbon atom at (3), as shown by the optical rotatory power We have seen that the asymmetrical carbon atoms at (1) and (2) in the *cinchonine and quinine series are all similar and therefore need not be considered further In the formation of cinchotoxin and quinotoxin the asymmetry of the* carbon atom at (3) is destroyed and the parasiticidal action is also destroyed In cinchotenine and quitenine, on the other hand, the asymmetry is still preserved, yet these substances have no therapeutical value So that the asymmetry of this carbon atom is essential but not decisive

The lævorotatory alkaloids, quinine and hydroquinine, have a specific action on the malignant tertian parasite, whilst the dextrorotatory alkaloid quinidine (hydroquinidine has not been tested as yet) is more powerful than quinine in its action on the benign tertian parasite The corresponding lævorotatory isomeride cinchonidine behaves very similarly in its action on the benign tertian parasite Both these isomerides are much less toxic to man than quinine We therefore conclude from this chemical study that

(1) *The methoxycinchonines—viz , the quinine series—are* less toxic than the cinchonine series

(2) The hydro alkaloids are more stable

(3) That the *lævoratory alkaloid quinine is a specific for the malignant tertian parasite, whilst the dextrorotatory* alkaloid *quinidine is the best alkaloid* tested so far for the benign tertian *parasite*

Conclusion

Much more work will have to be done, both chemically and experimentally, before we can gain an idea of the exact action of these alkaloids on the malarial parasites The work is being continued under the Medical Research Council, and I may here take the opportunity to thank Dr H H Dale, F R S , of their staff, for kindly permitting me to work in his laboratory and for the very material help he has given me, both by his advice and by placing the resources of his laboratory at my disposal

EXFOLIATIVE DERMATITIS OCCURRING DURING ARSENICAL TREATMENT.

(*With a Note on Toxic Jaundice.*)

BY E. G. FFRENCH, M.D., F.R.C.S. EDIN.,
MAJOR, R.A.M.C.; LATE ACTING LIEUTENANT-COLONEL COMMANDING 51ST GENERAL HOSPITAL, FRANCE.

DURING nearly ten years' experience with arsenical preparations in various parts of the world many thousands of cases of syphilis have come under my supervision, and it is my opinion that *severe* cases of exfoliative dermatitis and toxic jaundice occur only in a very small fraction. From time to time cases of erythema occurred after one or more injections, but this condition soon disappeared; the erythema has the appearance of a scarlatiniform or morbilliform rash, and has frequently been mistaken by inexperienced medical officers for scarlet fever. In some cases it is accompanied by high pyrexia, 104 or 105°, but more often than not it is comparatively mild. It may also be mistaken for German measles, and acute cases become severely ill. Desquamation follows these cases.

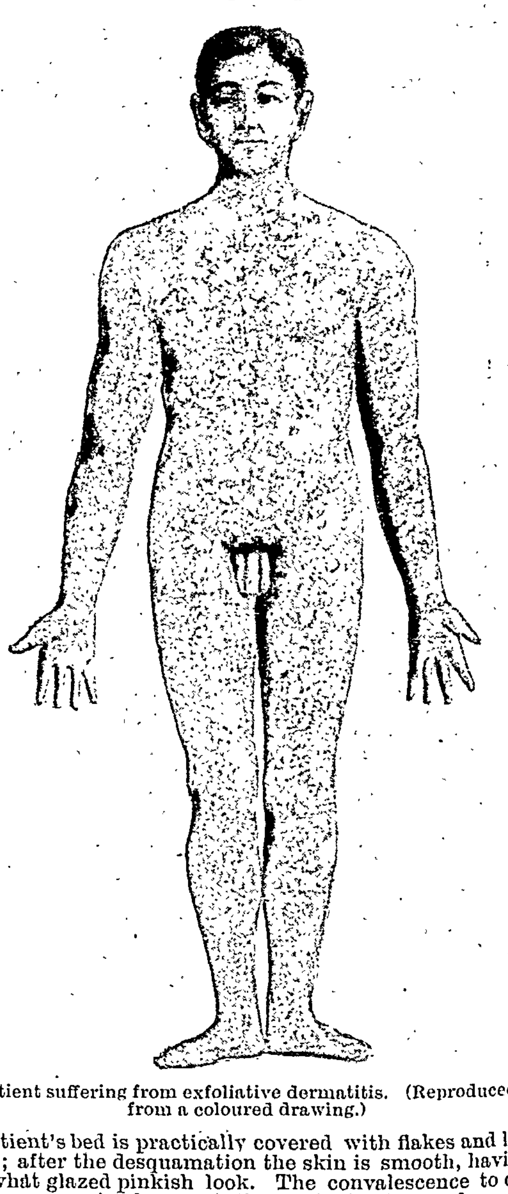
The erythematous condition in mild cases may be limited to a part of the body—for example, the neck or chest and abdomen. In severe cases it spreads over the whole of the body, and if it then develops into exfoliative dermatitis a very severe condition has come about and the patient's life is in danger. Both these conditions come on at varying periods during the course of treatment. Some patients will develop severe dermatitis after the second injection of 0·6 g. N.A.B.; others later in the course. Sometimes it makes its appearance immediately after the course of seven weekly injections of 0·6 g. N.A.B. I have never seen it develop later than a month after completion of treatment.

During several years in India and London I saw only four cases of severe exfoliative, but during service in France I had some 20 cases under my supervision. I feel convinced that the majority of these cases were due to exposure to cold. The conditions could not be as comfortable as in hospitals at home and the patients were less protected. Practically all the cases occurred during the winter months, and, morever, the fact that only two officers out of close on 2000 under treatment for syphilis developed severe dermatitis was significant. The officers had more comfortable accommodation and were able to go to a warm bed immediately after the injection and remain there for 24 hours. Although warm spring beds were provided for the soldiers for the first 24 hours after the injection, it was most difficult to keep them there owing to the large numbers undergoing treatment.

The Clinical Picture.

In severe exfoliative dermatitis the whole body is usually covered with a scarlatiniform rash, but somewhat darker in colour. This sometimes becomes confluent over parts of the body. Not infrequently small blebs make their appearance behind the ears and on the neck. Pustules and blebs form all over the body, and after these have ruptured crusting and scaling develop. Itching is very troublesome and becomes a burden to the patient. There is always a great deal of swelling of the face, involving the lips, nose, eyelids, ears, and cheeks. The conjunctivæ become very inflamed, lachrymation and photophobia being particularly troublesome. A weeping eczematous condition is nearly always present in some parts of the body, the ears, lips, axillæ, pubis, and scrotum being frequently affected in this way. The eyelids are very often so swollen that the patient is unable to see. The skin takes on a deep reddish-brown tint and there is a great deal of exfoliation of the epidermis subsequently. The weeping eczema and the presence of large pustules in various parts of the body, especially in the axillæ and groin, are two most distressing complications. When the acute stage is passed the skin is deeply pigmented and is harsh, thin, and atrophic. The scalp becomes swollen and eczematous, and settles down after a time with almost complete loss of hair, which grows again in the course of a few months. The eyelashes are frequently shed, but grow again. The soles and palms develop thick epidermic plates (hyperkeratosis), which are completely shed during convalescence; the nails also become affected. In a few cases there is high fever and headache, with diarrhœa, retching, and vomiting of bile-stained fluid. The patient usually looks and is very ill; the fauces are congested and the tongue is dry and brown. Owing to the loss of sleep due to the irritation of the skin condition and the toxic state of the patient his health becomes very much impaired, and he goes down hill rapidly. Œdema of the lungs and bronchopneumonia often complicate these cases and cause the fatalities.

In some of the severe cases the eruption is hæmorrhagic in several parts of the body. There is always marked general adenitis, and the glands, especially those of the axillæ, get very large, soft, and tender; not infrequently they break down. The urine nearly always contains a small amount of albumin. During the process of desquamation the patient's bed is practically covered with flakes and large scales; after the desquamation the skin is smooth, having a somewhat glazed pinkish look. The convalescence to complete recovery is slow, but the patient often makes rapid progress after the acute illness. As soon as the symptoms have subsided his appetite, which is very poor, improves markedly, and he begins to take an interest in himself. The depression, which is a characteristic feature, disappears and his general health steadily improves. After the desquamation is complete the patient is very much altered in appearance, and it is doubtful if his best friend would recognise him at first sight. However, after three or four months he regains nearly all his characteristics and looks like a normal individual again.



Patient suffering from exfoliative dermatitis. (Reproduced from a coloured drawing.)

Prognosis.

The prognosis is favourable when appropriate treatment is applied as soon as the condition is diagnosed. Lung complications not infrequently develop in spite of all precautions, and in these cases the prognosis is bad. It is my experience that the more severe is the skin affection the greater the internal complications, which put the patient in great peril of his life. Of the three cases who died with lung complications all had the most extensive and severe dermatitis imaginable The mild cases responded to intramine readily, and I have never seen any appreciable internal complications in any of them

Treatment

In cases where the *eruption is one of simple erythema—lotio calamine calamine cream and bran baths* Intramine I consider the best remedy, 2 5 c cm of intramine being given intramuscularly in the buttock in the same manner as an intramuscular injection of mercury This is repeated every fifth day until the disappearance of the erythema in simple cases or the exfoliation in severe cases In mild cases two doses will be sufficient, but in severe cases five to ten doses are often required I commenced the use of intramine in these cases in 1917 and have used it in every case since then At first Mr J E R McDonagh, who was then working in the same hospital and who introduced the drug to the profession advised the full dose of 5 c cm of the original preparation, but we found that this produced too much reaction and decided to make the dose 2 5 c cm After a little experience it was found that this dose produced little or no reaction, and could be given at intervals of five days without inconvenience to the patient After a time Mr McDonagh put up his *preparation in two separate tubes* which had to be mixed before injection For convenience I have been using 3 c cm of the mixture for each dose The drug acted quickly, producing most satisfactory results In some cases an appreciable amount of discomfort at the site of injection for 24 or 48 hours was noticed by the patient, and in nearly every case the temperature rose 2° and fell on the following morning, and did not rise again until the next dose was given It is thought that dermatitis is caused by *over-oxidation of the tissues of the body* by arsenic and as intramine acts as a reducing agent in the body it produces good and speedy results In those cases of generalised erythema with hyperpyrexia (105°) and headache venesection has proved most satisfactory and has aborted the severe symptoms From 10 to 15 ounces of blood should be withdrawn but, unfortunately, venesection does not prevent all cases from developing severe symptoms However it should always be carried out *as early as possible in these acute cases*

When the stage of pustular eruption develops ichthyol ointment 10 per cent , or lead and zinc paste, are very valuable applications, for the weeping eczematous condition calamine lotion, zinc oxide and starch lotion and zinc oxide ointment, at a later period, calamine powder is also useful For the conjunctivitis two or three drops of argyrol 25 per cent dropped into the eyes morning and evening effect a speedy cure Boric *lotion should be used after the argyrol Before the introduction of intramine the above local* remedies were the chief ones in use for treating cases of exfoliative dermatitis and recovery took many months Nowadays with the use of intramine an amino sulphur compound, they recover in one quarter of the time

The diet should consist of milk and soda plenty of barley water, milk puddings of all kinds Lime water should be added to the milk if *there is diarrhœa or digestive* disturbance Meat *meat* extracts, and *eggs* are contra indicated Tonics should be prescribed Further treatment with arsenic is commenced during the convalescent period, the patient by this time has desquamated, is feeling fairly well, and is able to walk about the ward Only half the original dose is administered weekly—namely 0 3 g N A B The patients invariably do well afterwards I have used all the arsenic preparations at different times but with the exception of four all the cases occurred in France where N A B was the preparation in use

Post mortem Findings of the Three Fatal Cases of Exfoliative Dermatitis

CASE 1 —Brain A little thickening of the pia at the vertex—otherwise normal Lungs Broncho-pneumonia right lower lobe otherwise œdema some small amount of pus in small tubes Heart 8½ oz small firm No V D H Kidneys 8¼ oz large flabby pale cortex not narrowed—much paler than the medulla Capsule strips with ease surface pale and smooth Large white kidney Spleen 8½ oz congested Spinal cord Normal Liver 52 oz pale fatty No subserous hæmorrhages Marked exfoliative dermatitis

CASE 2 —Skin Petechiæ Lungs Both lungs œdematous No consolidation Heart 10½ oz pale soft No V D H Liver 74½ oz large pale and a little fatty Spleen 9 oz not normally beyond its size Kidneys 6 and 6½ oz cortex streaked a little injected Cortex strips naturally surface smooth No subserous hæmorrhages Marked exfoliative dermatitis

CASE 3 —Skin Petechiæ Lungs Several infarcts in each with a little surrounding broncho-pneumonia and overlying pleurisy No fluid in pleura Subpleural petechiæ Heart 9½ oz dilated pale very soft No V D H Liver 59 oz somewhat fatty Spleen 7 oz not abnormal Kidneys 6 and 6¼ oz pale not swollen Capsule strips naturally Marked exfoliative dermatitis There was severe inflammation of the whole of the alimentary canal which prevented easy swallowing and digestion this patient had to be fed per *rectum a few days before his death* He was admitted suffering from severe secondary syphilis with involvement of the iris He did remarkably well until a few days after the completion of his course when dermatitis developed In spite of early treatment with intramine *he got rapidly worse*

The dermatitis in all three cases occurred within a month of completion of a course of moderate doses—viz , 0 6 g N A B *Cases 1 and 2 were readmitted suffering from* lung complications

TOXIC JAUNDICE

I am of opinion that there are certainly two types of jaundice occurring during the early stages of syphilis

First type —The jaundice not infrequently appears before treatment with arsenic There are some medical officers who persistently attribute every case of jaundice in syphilitics to arsenic compounds I have *seen those medical officers enter* a ward containing special cases and ask as they go up to the bedside of the patient with jaundice How many doses of "606 has this patient had? When told that the patient has not had any arsenic preparations, being only a recent arrival, they look astounded Having *treated venereal diseases for over* 20 years I have noticed *many* cases of *mild* jaundice in patients suffering from syphilis We always used to consider that syphilis caused the jaundice there being no specific arsenical preparations in those days to put the blame on Several cases have been noticed after the first two or three injections of arsenic This comparatively mild jaundice is no doubt, due to a widespread fatty degeneration of the liver cells caused by toxins of the *Treponema pallidum*

Second type —What is really arsenical jaundice comes on towards the end of the course of seven weekly injections of 0 6 g N A B In all probability it is due to the syphilitic degeneration of liver cells as well as to the toxic action of arsenic The jaundice is intense, the patients become seriously ill and the disease is very liable to end fatally unless prompt treatment is applied This type of jaundice is the result of an intense catarrh of the minute bile ducts *The colour of the skin and conjunctivæ is of* an intensely deep yellow—urine yellowish brown or dark brown stools very pale Fifteen cases of this toxic type came under my supervision from time to time, two of whom ended fatally

Treatment

In both the mild and severe cases I consider that intramine is the best remedy we have at our disposal It is given intramuscularly into the buttock and in doses of 3 c cm at intervals of five days In mild cases two doses are sufficient, but in the more severe cases as many as ten injections have *been given* I *believe I am right in saying that intramine* was first used in treating jaundice in 1917 at No 51 General Hospital Mr McDonagh and I decided to employ it in all cases suffering from jaundice Arsenical preparations in half the usual dose were given to the patient as soon as the jaundice cleared and were continued until the full amount of the course was completed Other remedies such as sodium sulphate calomel and bismuth and *soda* were also administered *The intramine in these* cases also acted as a reducing agent

Post mortem Findings of Two Cases of Toxic Jaundice

CASE 1 —Brain A little excess of cerebro spinal fluid and a smell *of acetone otherwise normal* Skull Shows irregular ossification Lungs Subpleural petechiæ and hæmorrhages a few interstitial hæmorrhages œdema no consolidation Heart 7 oz small subpericardial hæmorrhages Muscle not soft No V D H Liver 25 *oz* very small brownish with many slightly raised greenish areas these are found on section to blend and occupy large areas of the total liver Spleen 7½ oz , large soft, and pale Structure not recognisable Kidneys 4¾ and 5 oz , yellow and swollen cortex Kidney as a whole is small Capsule strips naturally Stomach Submucous hæmorrhages also hæmorrhages in omentum and behind peritoneum of posterior abdominal wall A subserous hæmorrhage *in the ileum* Sir John Rose Bradford the consulting physician of the area witnessed the post mortem examination and expressed the opinion that the condition of the liver was not true yellow atrophy The above was a case of a *congenital syphilitic showing bossing of the skull and saddle-back nose who developed a typical syphilitic* chancre after exposure On account of his very light weight he was only given 0 45 g doses of N A B and developed his jaundice after the *fourth injection* Intramine *was given but had no* appreciable effect

CASE 2 —Brain normal Heart 8½ oz subpericardial hæmorrhages No V D H Lungs Œdema in both hæmorrhages into the subpleura Liver 27 oz very small brownish in appearance with greenish areas similar to first case Spleen 7 oz somewhat pale and soft structure becoming unrecognisable Kidneys 5 and 5½ oz , cortex swollen and pale capsule not adherent Stomach Hæmorrhages behind the peritoneum of posterior *abdominal wall* submucous hæmorrhages Jaundice appeared after the sixth injection of 0 6 g N A B

The post mortem examinations were carried out by Dr. T H G Shore, then pathologist Etaples Area, France

---

INFLUENZA OUTBREAK AT SIMLA —With the sudden advent of warmer weather, influenza which has been smouldering for some time past has now broken out somewhat acutely The Indian quarters are most affected Influenza has appeared also in the neighbouring States where *the mortality rate is considerable* The local authorities have *issued a notice inviting attention to methods of prophylaxis*

AGGLUTINATION EXPERIMENTS WITH TRENCH FEVER RICKETTSIA.

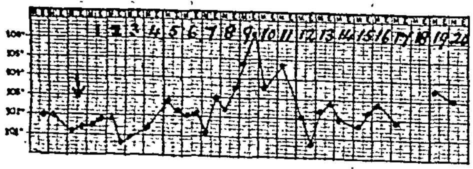
BY J. C. G. LEDINGHAM, C.M.G., D.SC., M.B.
(*From the Lister Institute, London.*)

ON my return from service in May, 1919, I was requested by Sir David Bruce, Chairman of the War Office Trench Fever Committee, to give some assistance in connexion with this inquiry. I proposed to take up the question of the transmissibility of the trench fever virus to laboratory animals. Experiments with this object had, in the hands of previous workers been attended with complete failure to demonstrate any unequivocal pyrexial phase commencing after a definite incubation period. I may say at once that my own experiments with rabbits and guinea-pigs inoculated either with trench fever blood supplied by infected volunteers at the New End Military Hospital or with infective lice excreta, proved in the main negative, in so far as the onset of a definite febrile phase following a definite incubation period was concerned. In a few instances, however, a striking pyrexial phase did intervene after a definite apyrexial period, and while I am fully cognisant of the difficulty of interpreting temperature charts in small animals, where pyrexial phases only are available as evidence of successful infection, the charts in the few cases mentioned were, in my opinion, strongly suggestive of a successful transmission of the virus. The chart of one of these apparently successful inoculations in the rabbit is appended for reference, while the general question of the transmissibility of trench fever virus to animals is postponed to a later period when further evidence may have accumulated. It is, of course, obvious that until we find some susceptible laboratory animal further research into the nature and properties of the virus will be greatly hampered.

The protocol of the experimental rabbit whose chart is attached was as follows:—

Rabbit. Weight, 980 g. Inoculated August 13th, 1919, intravenously with a saline emulsion containing 3 mg. of infective lice excreta. (Three other rabbits, each of which received the same dose at the same time, showed no definite pyrexial phase.) On August 22nd, when the fever had reached its height, blood was taken for a passage experiment, but the two animals inoculated intravenously therewith showed no definite pyrexial phase. Some guinea-pig charts are also appended below.

CHART 1.



Rabbit. Received lice excreta intravenously on day indicated by arrow.

Agglutination of Rickettsia.

While such experiments were in progress, it was considered desirable to ascertain whether the sera of animals which had received inoculations of infective lice excreta in saline emulsion showed any immunity reaction in test-tube experiments when brought in contact with such emulsions. If it could be shown that the rickettsia present in such emulsions were agglutinable by the sera of animals inoculated with infective lice excreta, whether a definite fever resulted or not, the evidence would certainly be of value in bringing the rickettsia into line with other formed micro-organismal bodies in the matter of the ordinary physiological immunity responses.

So long ago as 1909 Ricketts[1] was able to demonstrate that the rickettsia bodies contained in saline emulsions of the crushed eggs of the *Dermacentor* responsible for the transmission of Rocky Mountain spotted fever were agglutinated not only by the sera of guinea-pigs after recovery from a tick infection, but also by sera obtained from human cases.

His emulsion for agglutination purposes was prepared by crushing 40 to 50 eggs of *Dermacentor* in 0·05 c.cm. of salt solution. Hanging drops were prepared, and after two hours' incubation the drops were dried, fixed in absolute alcohol, and stained. With the sera of three recovered guinea-pigs agglutination occurred in dilutions up to 1 in 160, while normal guinea-pig sera produced only slight agglutination in dilutions up to 1 in 10. The three human sera tested had been kept for varying periods in the cold room, and while inhibition zone phenomena were manifested, agglutination of rickettsia was evident in dilutions varying from 1 in 40 to 1 in 200. Normal human sera, on the other hand, did not agglutinate the rickettsia in such emulsions in dilutions higher than 1 in 10.

Otto and Dietrich[2] have also during the late war obtained evidence of the agglutinability of typhus fever rickettsia present in the intestinal contents of infected lice by the sera of immunised rabbits and of typhus patients.

The intestinal contents of the infected lice were repeatedly washed and shaken and finally passed through a hardened filter. By this means a homogeneous emulsion of rickettsia was obtained. The results were read under dark-ground illumination. The sera of rabbits immunised with intestinal contents of infected lice (1 in 2 to 4 lice at intervals of 3–5 days) acquired a titre of 1 in 200. Data are also recorded with the sera of two typhus cases, one of which agglutinated rickettsia completely (++++) in a dilution of 1 in 50 and definitely (++) in 1 in 100, while the other gave a (++) reaction at 1 in 50 and a (+) reaction at 1 in 100. Of the control human samples tested they observed that the sera of two Volhynian fever convalescents gave some agglutination (++) at 1 in 50, but little or none at 1 in 100.

Agglutination of Trench Fever Rickettsia.

Preparation of emulsion of rickettsia.—About 10–20 mg. of the dry lice excreta supplied to me by Mr. A. W. Bacot and Dr. J. A. Arkwright from lice fed on experimentally infected trench fever patients at the New End Military Hospital were ground up very thoroughly in an agate mortar with saline containing 1 in 500 formalin. The excreta were simply moistened with the saline at first and with the mortar converted to a thick brown ropy mass. More saline was added gradually and the material thoroughly emulsified. The volume was then made up to 10 c.cm. according to the richness of the original material in rickettsia bodies. On standing a brown precipitate falls very rapidly, and the process may be hastened by centrifuging for a few minutes. The supernatant portion is a brownish-yellow opalescent fluid which should contain no gross particulate matter visible to the naked eye. A drop of this fluid when evaporated and appropriately stained should show the rickettsia bodies standing out clear and discrete, without trace of clumps, on a clear background.

Technique of agglutination test.—Having secured a satisfactory emulsion of rickettsia one prepares dilutions of the sera to be tested, which are then mixed in equal parts with the rickettsia emulsion (generally one drop of each from a dropping pipette either in dwarf test-tubes or in hanging drops in a moist chamber) and placed in the incubator at 37°C. for at least four hours. After incubation a drop from each tube is placed on a slide and allowed to evaporate on the top of a copper paraffin oven (at 50–60°). The slide is then placed for half an hour in an acid alcohol bath (1 per cent. HCl in abs. alc.), washed in running tap-water for at least ten minutes, and finally stained in the inverted position in a Giemsa bath containing one drop of the fluid stain to 1 c.cm. of a mixture in equal parts of tap and distilled water. The staining should be prolonged for at least 18 hours.

This modified Giemsa technique, for which I am indebted to Dr. Arkwright, proved far superior to that which I had originally employed in demonstrating discrete or clumped rickettsia in evaporated drops. By the use of acid alcohol fixation, followed by thorough washing, much of the protein precipitate, whether coming from the lice excreta emulsion or from the agglutinating serum, was got rid of, while the rickettsia stood out brilliantly defined on a clear background.

Results.

The first test to determine whether rickettsia could be made to agglutinate at all was made on August 25th, 1919, with the following sera:—

(1) Four rabbit sera taken on the twelfth day after inoculation with lice excreta. The chart of one of these is shown above.

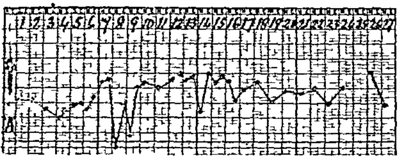
[1] Ricketts, H. T.: Journ. Amer. Med. Assoc., 1909, lii., 379.

[2] Otto, R., u. Dietrich: Deutsch. med. Woch., 1917, 577.

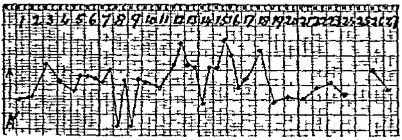
(2) Serum of Guinea pig A on the nineteenth day after inoculation intraperitoneally with lice excreta. The temperature chart of this animal is attached along with that of another guinea pig (A') inoculated similarly on the same day (August 6th). These two charts are strikingly similar and both present a saddle back effect with collapse readings between the seventh and tenth days.

CHART 2



Guinea pig A Received lice excreta intraperitoneally on day indicated by arrow

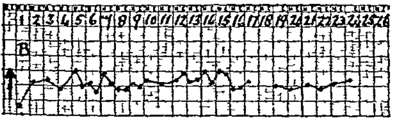
CHART 3



Guinea pig A' Received lice excreta intraperitoneally on day indicated by arrow

(3) Serum of Guinea pig B on the nineteenth day after subcutaneous inoculation with lice excreta. Annexed temperature chart showed little oscillation.

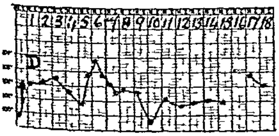
CHART 4



Guinea pig B Received lice excreta subcutaneously on day indicated by arrow

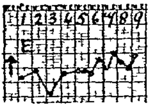
(4) Serum of Guinea pig C on nineteenth day after intraperitoneal inoculation with lice excreta. Temperature chart showed no oscillations.

CHART 5



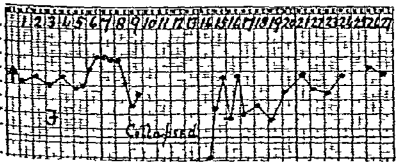
Guinea pig D Inoculated on day indicated by arrow with blood from E (Intraperitoneal.)

CHART 6



Guinea pig E Received lice excreta intraperitoneally on day indicated by arrow. Killed on ninth day. Blood passaged to D.

CHART 7



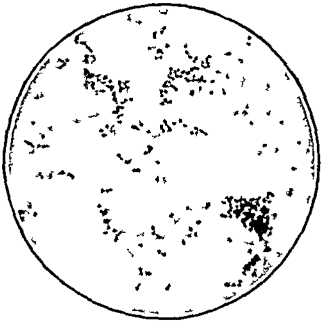
Guinea pig F Received lice excreta intraperitoneally on day indicated by arrow

(5) Serum of Guinea pig D taken on the tenth day after intraperitoneal inoculation with blood from Guinea pig E. This latter animal was killed on the ninth day after intraperitoneal inoculation with lice excreta in order to provide blood for passage experiment. Another animal Guinea pig F which received the same dose as Guinea pig E on the same day, showed a striking chart which is reproduced along with those of D and E. Guinea pig F was in a state of collapse for four or five days following the first febrile phase which commenced on the sixth day after inoculation. During the collapse phase, when subnormal temperatures were registered all the abdominal hair came away.

All the above sera were tested in dilution of 1 in 10, and two normal guinea pig sera and two normal rabbit sera were used as controls. Complete agglutination of rickettsia took place with the four experimental rabbit sera and with Guinea pig A. The other guinea pig sera produced practically no agglutination or, at the most minute clumps while the films prepared from the control sera showed absolutely discrete unclumped rickettsia.

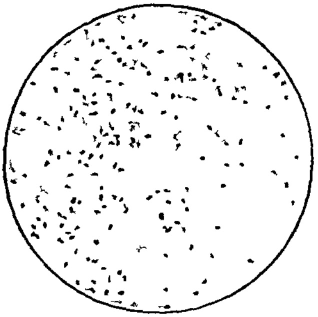
The experiment was repeated on several occasions in the case of the rabbit series and agglutination was found to disappear beyond a dilution of 1 in 40.

FIG. A.



Agglutination of trench fever rickettsia by immune serum (× 2000)

FIG. B.



Control emulsion of unclumped rickettsia (× 2000)

The question then arose whether a reaction of this kind could be explained as a non specific agglutination of rickettsia occurring in the course of the interaction of immune serum with the louse protein matter contained in the emulsions with which the animals were inoculated. To settle this point two rabbits were immunised with lice excreta containing rickettsia and two with normal lice excreta. Three injections were given on Sept 4th, Oct 27th, and Oct 31st, about 10 mg being the dose on each occasion. The animals were bled on Nov 6th and the sera titrated, with the result that the sera of the animals inoculated with the infective lice excreta agglutinated rickettsia in so high a dilution as 1 in 300, while those immunised with the excreta of normal lice gave mere traces of agglutination at 1 in 5.

The annexed micro photographs for which I am indebted to Dr Duncan Reid, show the appearance of rickettsia when clumped in the presence of immune serum and in the control unclumped state (magnification 2000).

Owing to the apparent disappearance of trench fever it has not been possible so far to obtain samples of blood from recent cases in order to ascertain whether the reaction possesses a diagnostic value. The only material available has been derived from old cases of 6-12-18 months' standing with symptoms of "chronic" trench fever. For this material I am indebted to Dr. J. L. Dimond at the New End Hospital. None of these cases gave a reaction even in 1 in 5 dilution. Further data, however, may be obtained from the investigation on serological lines of experimentally infected volunteers, and more especially passage cases inoculated with infective blood.

Summary.

(1) Experiments (about 50 in all) undertaken with the object of transmitting trench fever virus to laboratory animals proved in the main negative. A very small minority of inoculated rabbits and guinea-pigs, however, exhibited temperature charts which at least suggested a successful transmission of the virus. The question must for the present remain undecided, but it is probable that a certain small percentage of normal rabbits and guinea-pigs may be susceptible to the virus.

(2) In the course of the work it was established that the rickettsia bodies present in the excreta of lice fed on trench fever patients are agglutinated in the presence of immune serum obtained from animals immunised with infective lice excreta.

(3) Trench fever rickettsia are not agglutinated by the serum of animals immunised with the excreta of normal uninfected lice.

THE VALUE OF POSTURE IN THE AFTER-TREATMENT OF "STIFF-SHOULDER."

BY CHARLES MACKAY, M.D. MELB.,

LATE LIEUTENANT-COLONEL, R.A.M.C.; LATE OFFICER IN CHARGE, DEPARTMENT OF MUSCLE RE-EDUCATION, ALDER HEY SPECIAL MILITARY HOSPITAL, LIVERPOOL.

WHETHER the disability be caused by a compound or simple fracture in the neighbourhood of the joint, by a severe dislocation, by a primary weakness of muscle through injury of the nerve-supply to the deltoid, trapezius, serratus magnus, or by secondary muscle-wasting, a not infrequent result of injury to the shoulder is the so-called "stiff-shoulder."

A criterion of the functional result following treatment of an injury of this character would be evidenced by the ability of the patient when standing up, firstly to abduct the arm to a right angle, on a horizontal plane with the shoulder, then to rotate the arm externally, and finally to raise it vertically above the head. These movements, so apparently simple in health, are very easily lost; their mechanism is delicate and complicated, and a loss of function of one of its component elements may be sufficient to nullify the activity of the remainder.

The expression "stiff-shoulder" is used in this article to mean one at which the greater part of this normal range of voluntary movement is not obtainable; in which attempts at passive movement apparently produce pain, are resented by the patient, and are often voluntarily resisted. It is not intended to apply to old cases of rheumatoid arthritis, nor to the pathological conditions subsequent to severe injuries and acute inflammatory mischief in the joint itself, with the formation of definite articular adhesions and osteo-arthritic changes limiting movement. In the type of "stiff-shoulder" which is here referred to the main causative factors interfering with normal function are considered to be the weakness of the muscles which abduct, externally rotate, and elevate the arm, and in a percentage of cases the chronic contraction with shortening of the muscles which adduct and internally rotate the limb. Additional factors in some cases are the presence of periarticular adhesions in the surrounding structures of the joint, causing pain on movement, and, what is often very important, the persistence of a hysterical element, the result of prolonged disuse and previous painful experiences.

A disablement of this description which has existed for any length of time presents a difficult and often very unsatisfactory subject for treatment; it is accompanied by an amount of muscle-wasting and loss of function which seems to be out of proportion to the extent of the original injury. The usual history in this type of case is that of an accidental injury to the shoulder some months previously, treated by flexion of the arm, which was bound to the side. Subsequently difficulty was experienced in getting the arm away from the side and above the head; this has persisted in spite of treatment by massage, electricity, and movement of the arm under an anæsthetic. The patient complains that the arm is painful when movement is attempted and is practically useless; on inquiry it is found that no abduction arm-splint has been worn, and that no attempt has been made to minimise the effect of gravity or gradually to restore function in the horizontal posture.

The Mental Element.

In many cases of weakness of the muscles of the shoulder-girdle I have found what one might call a definite mental element in the disability; in some patients this is manifested by the adoption of an anxious resistive attitude, and in others of a passive apathetic one. In whatever way this condition is exemplified, however, the result is that the disability is exaggerated, and the difficulties of treatment correspondingly increased.

The treatment of the original injury will necessarily be surgical, and will probably entail a varying period of immobilisation on some form of retentive apparatus. To facilitate early recovery of abduction and elevation an abduction rectangular arm-splint of some kind should be used whenever possible. Todd, speaking of the present after-treatment of dislocations of the shoulder by fixation of the arm to the side, condemns it as being irrational, unscientific, and in actual practice unsuccessful.

In my opinion the best type of abduction arm-splint is the one described and illustrated by Dr. W. Colin Mackenzie in the *British Medical Journal* of Feb. 24th, 1917, and stated to have been introduced by him in 1908. This splint should be made for the individual patient, and it can be adjusted and modified to suit varying types of shoulder injury; its obvious advantages are its ease of application and removal, with the constant support which it gives to the muscles of the shoulder-girdle. When immobilisation is completed the difficulties of the after-treatment will greatly depend upon whether a suitable abduction arm-splint has been worn or not. In the former case recovery of movement may be rapid and comparatively easy, in the latter correspondingly slow and difficult. One of the reasons for this striking difference is that the splint will have prevented any contraction and shortening of the adductor and internal rotator group of muscles, while at the same time resting without stretching their important opponents.

Gravity an Important Factor.

In treating the original injury and in attempting to regain movement at the shoulder-joint it is all-essential to recognise the very important part played by gravity. Text-books do not lay sufficient stress on this factor, and it is apt to be forgotten that the weight of a muscular arm may be from 10 to 14 lb. If after an injury to the joint or its neighbourhood the arm be left mainly unsupported as regards its own weight, the constant dragging pull exerted by gravity will greatly aggravate any reflex atrophy of the shoulder-girdle muscles; this condition may become so marked in old cases as to produce a sub-luxation of the humerus. In this connexion it is important to lay stress on the point that muscles, not ligaments, are the primary supporting structures of a joint such as the shoulder. The deltoid muscle especially—one of the main supports of the shoulder-joint—has acquired a sinister reputation for rapid wasting which is unequalled by that of any other major muscle in the body.

In all injuries in this region an important point to remember is the preservation of the insertion of the deltoid; if this has been lost at the time of injury the resulting disability, as instanced by Bland-Sutton, will, in spite of any after-treatment, necessarily be very great. The deltoid and the trapezius are here regarded as the essential muscle factors in any attempt to regain movement at the shoulder-joint by rest and muscle re-education; one or other having been lost the utility of the arm is very greatly diminished. When the surgical condition of the injury allows of an attempt at movement the removal of the splint should be very carefully supervised, and the patient then made to lie flat on a wide couch—30 inches—with a low pillow under the head and neck.

The Essential Principle in Treatment.

The line of treatment here advocated is simple, and its very simplicity perhaps accounts for its comparative neglect; with personal modifications it follows the plan of muscle re-education advised by Dr. Colin Mackenzie in his recent work on the "Action of Muscles."

Its essential principle is to encourage any possible amount of voluntary movement and to treat the patient at the beginning in the lying-down horizontal position. This position helps considerably to eliminate two important factors retarding recovery of movement, gravity—the weight of the arm—and muscular spasm. It is necessary to obtain muscle relaxation before the attempt at voluntary movement is begun, and in the horizontal position this relaxation can be most easily obtained. With the elbow flexed and the forearm supported, the patient is then encouraged to abduct the arm farther and farther away from the side and afterwards gradually to elevate it. In order to facilitate movement in difficult cases cardboard powdered with chalk may be placed under the arm to diminish frictional resistance. These attempts to obtain voluntary movement should be carried out once, twice, or three times a day on a firm support, table or couch, and for a variable period depending on the weakness of the muscles and on the ability of the patient to concentrate his attention on the muscular effort involved. Once full abduction and elevation of the arm have been obtained in the lying-down horizontal position, it may be definitely stated that it is only a question of time before full movement will be obtained in the upright vertical position. This result, however, can only be achieved gradually, and progress is accomplished by slowly elevating the head and shoulders of the patient either on pillows or by means of a special couch. Each elevation is regarded as a stage in the re-education process, and perfection of movement must be obtained at any one stage before proceeding to the next highest one. Even if the difference in elevation be only a few inches, it may be too much at first for the weak muscles.

It is wise to begin each daily period of exercise in the horizontal position, and gradually to work upwards to the highest elevation previously reached. The muscles are by this means enabled to accommodate themselves to their load, better results are obtained, and initial disappointment to the patient is avoided.

Methods of Dealing with the Disablement.

In the old-standing type of stiff-shoulder the problem has to be approached in two ways: firstly, to gain the patient's confidence that curative, or rather ameliorative, procedures are possible; and secondly, to place the affected muscles during treatment in such a position that their work begins at a minimum. Mackenzie rather aptly calls this the zero position, and Professor Arthur Keith has named it the minimal load position. It may be stated that the patient's mind has to be stimulated as to the value of personal effort, and through his mind his muscles have to be re-educated to enable them to regain as much of their lost power and coördination as possible. Misdirected effort resulting in spasm must be constantly avoided, and in this field of activity there exists plenty of scope for both physical and psychical re-education. It is not pleasant to see the attempts which are sometimes made in these cases of stiff-shoulder to diagnose and treat the condition, the rough handling, the struggle between patient and surgeon, the abortive attempts at passive movement, the movement under an anæsthetic, and the last condition remaining sometimes worse than the first. To examine a wasted shoulder after months or years of massage, electricity, and passive movements, and to find almost total absence of voluntary movement with a partially subluxated head of the humerus is to realise the limitations in these cases of many of our modern methods of treatment.

While drawing attention to what is regarded as a serious omission in the routine treatment of these patients, it is not implied that in skilled hands successful results have not followed the combination of other methods, such as, for example, the electrical treatment so strongly advocated by Bristow. It is suggested, however, that more rapid and beneficial results would follow if this positional aid to treatment were more universally adopted. It would scarcely seem necessary to point out—if it were not such a frequent occurrence—that all attempts at after-treatment of a stiff-shoulder in the sitting or standing-up position with the arm hanging by the side are contra-indicated as tending to perpetuate the disability, and to discourage the patient from attempts at voluntary movement.

Conclusion.

During nearly five years' war service, and while serving on medical boards for the Ministry of Pensions, I have seen numerous cases of shoulder injury whose after-treatment had, in my opinion, been carried out without due attention to anatomical principles of muscle rest and muscle re-education. By the kindness of Sir Robert Jones I was enabled to see and treat many cases of this nature while in charge of the Muscle Re-education Department at Alder Hey Military Hospital, Liverpool. My belief in the efficacy of the method of treatment now formulated was definitely strengthened by the results obtained there. It is considered that if voluntary movement in a correct anatomical position could have been combined during the war with the massage, electricity, and passive movements so extensively practised, the resulting civil inefficiency and consequent list of pension recipients would have been considerably reduced.

That active movement leading directly to a gradual return of previous full working activities is the ideal aim of all forms of treatment in this class of case would sometimes appear to be forgotten; too much is often done for the patient, and he is allowed to do too little for himself. Where opposing muscles have become contracted and shortened, or where peri-articular adhesions of a minor degree have occurred in the surrounding structures, the patient's own vigorous volitional efforts are the best means of gradually stretching the contracted opponents or of breaking down the adhesions. The use of force and an anæsthetic may be essential if time is an element, and if painful passive and voluntary movements can afterwards be borne by the patient; but I believe that better results will be obtained if treatment on the lines above indicated can be gradually carried out. Once movements have been obtained in the lying down position and gradually increased these may be strengthened, and final complete mobility of the joint obtained, on the lines of the active gymnastic exercises ably carried out by Colonel H. E. Deane, R.A.M.C., at Croydon.

By means of this paper it is hoped that the value of early splinting of the arm in an abducted position with a recognition of the value of the horizontal posture as an aid to any form of treatment, may be fully realised, and some little advance be thus made in the treatment of a notoriously difficult condition. Evolution and the adoption of the upright attitude are responsible for more than one of our modern difficulties of treatment.

RESIDENTIAL ANTE-NATAL AND POST-NATAL TREATMENT

AT THE LONDON LOCK HOSPITAL FOR WOMEN.

BY G. W. RUNDLE, L.R.C.P. & S. EDIN.,
HOUSE SURGEON, LONDON LOCK HOSPITAL FOR WOMEN.

OWING to the great importance of ante-natal and post-natal treatment and the interest attaching to the excellent results which have been obtained at the London Lock Hospital for Women, I venture to submit this short communication on cases delivered during the last 21 months. There have been 168 pregnant women delivered in the hospital during the above period; of these 92 were cases of syphilis and 76 were cases of gonorrhœa.

Syphilis.

Of our 92 cases of syphilis 5 babies were stillborn and 9 died in the early weeks after birth, the remaining 78 doing excellently.

The syphilitic cases admitted can be divided into six classes: (1) cases admitted late in pregnancy with marked clinical signs of generalised syphilis; (2) cases admitted early in pregnancy with the clinical manifestations of generalised syphilis; (3) patients admitted early in pregnancy with a primary sore as the only sign and a negative Wassermann; (4) cases admitted late in pregnancy with a primary sore and a negative Wassermann; (5) cases who had had a full course of treatment before they became pregnant; (6) cases admitted with no clinical signs, only a history of miscarriages, and giving a positive Wassermann.

Our bad results, we found, all belonged to Class 1. The babies in all the other classes did splendidly. It is impossible to say how many of the children born alive were (1) healthy, (2) syphilitic, as the Wassermann reaction of the umbilical blood proved paradoxical, and that of the infants' blood was almost invariably negative a few days after birth. It was found, as Mr. J. E. R. McDonagh had previously shown, that the blood does not become positive much before symptoms appear.

The Treatment of the Mothers and Infants.

A few of the infants were premature and had to be reared in incubators. In the treatment of the mothers two facts stood out: (1) the excellent manner in which they withstood large doses of arsenic and mercury right up to full term, when these were indicated; (2) the extraordinary tonic effect of treatment. Although most of the women on admission had stomatitis, which was not infrequently aggravated by the arsenic and mercury used subsequently, it proved no bar to energetic treatment owing to the readiness with which it could be kept in check by intramine. It was found that one or two injections of intramine would permit of the assimilation of much more mercury; in some cases as much as 10 gr. of pil. hydrarg. were taken daily with impunity, though previously signs of intolerance to the drug had been manifest. Our successful results were, undoubtedly, in no little part due to the incorporation of intramine in the routine treatment.

The arsenical preparations used were neodiarsenol and novarsenobenzene.

The modes of mercurial administration were pills by mouth, intramuscular injections of mercury (grey oil), and cyanide of mercury intravenously. The last method was employed at Mr. J. Ernest Lane's suggestion. It is interesting to recall that Mr. Lane commenced using cyanide of mercury intravenously as long ago as 1896, during which year he administered over 1000 intravenous injections, using the concentrated method, in a 2·0 c.cm. syringe. Thus the intravenous administration of concentrated solutions is not as novel as it is usually thought to be.

The details of this mercury cyanide treatment are as follows:—

One intravenous injection of a 606 substitute and five intravenous injections of a 1 per cent. cyanide of mercury solution made with double distilled water are given weekly, the initial dose being 10 minims, and this is increased to 15 minims and then to 20 minims or more if the patient shows no signs of idiosyncrasy, such as abdominal pain; this occurred in only 3 per cent. of cases treated by this method. The injections are continued for a course of eight weeks, and then a month's rest is given before starting another course. If the patient gets gingivitis, or loses weight, appropriate intervals of rest are given.

The amount of the mercury cyanide tolerated varied very much, one patient of 9 st. weight could take 50 minims daily intravenously without ill-effects. It was owing to the tonic effect of the treatment on the mothers that Mr. Charles Gibbs urged that the infants should be suckled whilst the mothers had a course of 914. The infants were placed to the breast immediately after the mother had her injections. This proved an enormous success; the infants' progress was better than when they themselves had intramuscular or intravenous injections of 914. If for any reason a mother could not suckle her baby novarsenobenzene was given intravenously to the infant.

A word about intravenous injections may be of interest. The external jugular vein was the site chosen; this vein, as Mr. Gibbs has often shown at his demonstrations at the London Lock Hospital, is generally to be preferred to the scalp veins or the superior longitudinal sinus through the anterior fontanelle. The child is placed in the horizontal position, its head rotated to one side and firmly held by an assistant; when the child cries the vein distends, and the needle point is then inserted. This site is convenient also for taking blood for Wassermann tests.

As to dosage of 914, Mr. McDonagh's standard for infants of a milligramme per pound weight was the initial dose used; this dose was increased as the child advanced in weight. Four premature infants were successfully reared in our electrical incubators, one baby weighing only 3½ lb. when born. The infants were fed on the four-hourly system—that is, five feeds in the 24 hours—and an eight hours' rest at night for both mother and child; the mothers thus got their natural sleep, and so secreted more milk.

At first there was some difficulty in getting the mothers to feed their babies, which, being in many cases illegitimate, were looked upon as encumbrances, but owing to the foresight of Mr. Gibbs prizes were offered periodically to the mother whose baby put on most weight. This competition quickly produced the desired results. When a mother left the hospital she was requested to report immediately she became pregnant again, as it has been found that the birth of a healthy child can only be guaranteed if the mother is treated throughout each succeeding pregnancy.

Our experience is that if syphilitic pregnant women would come up for treatment early enough 100 per cent. of the children would be born alive.

Gonorrhœa.

Considering how profuse was the discharge in most of the gonorrhœa cases treated and delivered in the hospital it is surprising that no complication, beyond an abscess in Bartholin's gland, was met with; pregnancy might have acted as a safeguard, but much of the success was undoubtedly due to the regular douching and swabbing out with Milton, recommended by Mr. Lane. This preparation is a strongly hypertonic saline solution, containing free hypochlorous acid in unusually high proportions; it is non-toxic to the tissues, and is a rapid solvent of pus and mucus. We use it, a tablespoonful to a pint, as a vaginal douche, and half a teaspoonful to a pint for bladder and urethral irrigations in cases of urethritis; we use it also (strength 1 in 10) for irrigating Bartholin abscesses and buboes after incision with most gratifying results.

It is most satisfactory to report that not a single case of ophthalmia neonatorum has occurred in the cases born in hospital, a result which redounds to the credit of the nursing staff. The moment an infant is born its eyes are washed with a 1 per cent. solution of silver nitrate, and if the eyes appear to be a little inflamed a day or two later collosol argentum (1 in 2000) is used as an eye douche, as it is less irritating than silver nitrate.

Collosol argentum is, in our experience, the best local remedy for cases admitted with gonorrhœal ophthalmia.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

CASE OF TUMOUR OF MESENTERY.

By J. K. Haworth, M.D., B S. Durh ,

RESIDENT MEDICAL OFFICER, ROYAL VICTORIA INFIRMARY, NEWCASTLE ON-TYNE , LATE CAPTAIN R A M C S R LATE SURGEON SPECIALIST EIGHTH LUCKNOW DIVISION

THIS case, I think, sheds a little more light on the interesting and rare conditions of mesenteric tumour

While doing duty as surgical specialist to 8th Lucknow Division, Rifleman H G , 1st Garrison Battalion, Royal Irish Rifles, aged 28 years, was sent to me from Cawnpore on August 12th, 1917, with a lump in his abdomen He had very few symptoms, but the presence of this tumour seemed to worry him On examination he was found to have a tumour about the size of a large tangerine orange, situated in the right iliac region, below and to the right of the umbilicus , it felt hard and circumscribed, and it was movable all over the abdomen He had no difficulty with his bowels, and apart from his tumour he felt fairly well A diagnosis of mesenteric cyst was made

Operation —The abdomen was opened by a vertical incision in the right semilunar line below the umbilicus over the tumour. A mass, yellow in colour, was seen in the mesentery rather nearer to its posterior than anterior attachment The cyst was in a favourable position with regard to vessels and was enucleated The mesentery was sutured and abdomen closed, other enlarged glands in the mesentery were felt and the case was considered to be tuberculous in origin On examination the tumour consisted of a thick firm homogeneous capsule containing semi solid caseous material and débris, no signs of any hairs or material suggesting a dermoid It was unilocular There was no minute pathological examination of the wall or contents Recovery was uneventful

My case is almost identical with the cases reported by Mr E L Pearce Gould,[1] except that I was able to make out other glands in the mesentery , this fact, I think, adds weight to Pearce Gould s supposition that these conditions are tuberculous in origin

THE BACTERIOLOGY OF COLITIS.

METHOD OF INVESTIGATION FROM INTESTINAL MUCUS INSTEAD OF FÆCES

By H L. Lyon Smith, M.D Durh

THE presence of mucus in the stools is the chief point in the diagnosis of colitis, as mucus is not a normal constituent of intestinal evacuations In taking the history of a case patients are usually found to be ignorant of the presence of mucus, with the exception of more severe cases where they have noticed slimy and abnormal motions The majority of physicians have been content to order a specimen of the fæces to be sent to the bacteriologist, who usually receives for examination purposes a small portion of a solid stool, from which he is expected to prepare a vaccine of the most conspicuous organisms It is the method which is required for distinguishing which foods have been digested or otherwise, but is too gross a one for the diagnosis of the bacterial factors in colitis The malady is not of the fæces, but of the intestinal mucous membrane, and the closer we get to the latter in our researches the more likely we are to discover the real nature of the pathogenic organisms concerned in the ætiology

The Method Described

It has been the practice of the writer for the last seven or eight years to ask the patient to have a Plombière douche and *from the* second washing flakes of mucus can be collected The rectum is first washed out with a pint of warm water and the fæcal discharge thus obtained *discarded* A second *irrigation is* then made with two or three pints of plain warm water slowly injected and allowed to remain in the intestines about six minutes whilst the patient turns from side to side in order to separate the adhering mucus This second wash-out is received *in a clean receptacle* and search is then made for flakes of mucus which are transferred to a sterile specimen bottle When received these flakes are poured out into a large Petri dish half full of sterile normal saline and examined against a black background *in order to obtain some* idea of the character of the mucus Under macroscopic examination these may be found in thin, pale brown soft flakes or, in other cases thick dark brown tenacious masses and in severe cases a complete *cast of the intestine may be found* To search for amœbæ, a portion of the membrane may be broken off and examined under a cover-glass on a warm slide Other fresh films are made and stained

Slide 1 —Stained by carbol thionin, which shows up clearly capsulated bacteria such as enterococci *B mucosus capsulatus* pneumococci or the longer chains of *Streptococcus mucosus capsulatus* It will also show if there are any ova of intestinal parasites

Slide 2 —Stained for T B

Slide 3 —Gram stained gives a differential estimation of the relative proportions of the Gram negative and Gram positive bacteria In most specimens of mucus from cases of colitis the latter exceed the former in numbers

For cultural purposes a small piece of the mucus is teased off with platinum needles put into a tube of sterile broth incubated at 37° for an hour then well shaken up and loops of this broth are subcultured on various media at the discretion of the worker The writer prefers to use (1) ordinary agar tubes, (2) glycerine agar (3) freshly made blood agar tubes (4) bile salt-agar plates, a very convenient preparation for making these being the Solmedia preparation of MacConkey s bile salt agar issued by Baird and Tatlock

The freshly made blood agar media enable one to pick out those small powerfully hæmolysing colonies of streptococci which are *extremely pathogenic and frequently the chief causes of dangerous* anæmias In one case of pernicious anæmia accompanied by colitis a vaccine of hæmolytic streptococci was the principal constituent of an antigen which proved most effective as shown by *the differential blood counts This occurred three years ago* and the patient is still in good health

The advantages of this method of examination over that in general use—namely, investigation of the solid fæces—must be evident, as it is possible for the bulk of the fæces to be evacuated without having ever been in contact with the inflamed intestinal walls, so that the pathogenic organisms responsible for the colitis may easily escape detection

A CASE OF FATAL INTERNAL LACERATIONS WITHOUT EXTERNAL WOUNDS.

By Walter E. Masters, M D. Brux , M R C S , L R C P

THE case here described is probably not unique, but it is significant that there should have been such severe internal injuries without as much as a bruise about the abdomen or chest , it is also remarkable that the boy should have lived for one and a half hours with the splenic vessels torn off

On April 19th, 1920, a healthy young adult African native fell down a mine shaft for a distance of 150 ft to the bottom He was brought to the Prestea Hospital and seen by me immediately, about half an hour after the injury He had a laceration of the dorsum of the left foot minor bruises of the legs, arms, and head of an insignificant nature Blood was *coming* from his penis, due to a rupture of the urethra near the prostate resulting from a blow on the scrotum during the fall The bladder was intact The foot wound was being dressed when the writer was suddenly called away The patient had said that he was not in much pain, and turned himself over while being dressed The writer returned in three quarters *of an hour and the boy* was dead having lived *for one and a half hours after the* injury

A post mortem examination was carried out There were no abrasions or bruises of any kind on the trunk, externally or internally On opening the abdomen three pints of red blood escaped The spleen four times its normal size, was badly lacerated near the hilum, the splenic vessels were completely *torn off*, but the spleen was not separated *from* its normal bed The cardiac end of the stomach was lacerated for four inches, and the stomach contents were free in the abdomen There was hæmorrhage into the pancreas and great omentum Death was due, of course to internal hæmorrhage

The rarity of the circumstances and the vitality of the subject seem to me to justify publication of the case

Prestea Gold Coast

ERRATA —In the article by Drs Dreyer and Burrell on the Vital Capacity Constants that appeared in our last issue some corrections arrived after we had gone to press On p 1213 near the middle of the first column "No 11 (see Table IIA)" should read "No 11 (see Table IB)", and the lines commencing *a few lines lower should read* (1) No 15 (2) No 55 (3) No 139, (4) No 157, (5) No 168 (6) No 176 (7) No 178, (8) No 196 (see tables), (9) No 115 (returned – 9 4 per cent early good case which did well) (10) No 164 (returned – 4 2 per cent a patient with indefinite signs and good condition, but in whom T B were found)

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

A MEETING of this section of the Royal Society of Medicine was held on June 4th, Mr. **J. D. MALCOLM**, the President, being in the chair.

Traumatic Laceration of Pedicle of a Fibroid.

In the absence of Dr. **PHILIP TURNER** Dr. **HERBERT WILLIAMSON** read his communication on a case of Traumatic Laceration of the Pedicle of a Fibroid, following a bicycle accident. A woman fell off her bicycle on to her left hip, which was bruised, and she was taken home in a bath-chair. The following day she had a rising pulse; the abdomen was tumid, with dullness in the left flank, and a hard tumour was felt rising out of the pelvis in the mid line. The diagnosis made was intra-abdominal hæmorrhage, probably connected with a calcified fibroid, and a laparotomy was performed 24 hours after the fall. The abdomen was found full of clots and blood, and on raising a hard, calcified, pedunculated fibroid attached to the fundus of the uterus the pedicle was found to be torn and bleeding, and was removed. The bleeding of two small arteries was checked, and the wound in the fundus closed. The patient made an uninterrupted recovery.

Rupture of the Uterus.

Dr. **J. FORD ANDERSON** described a case of Rupture of the Uterus followed by Recovery.

Mrs. E., aged 33, a 4-para (one miscarriage), was sent to a maternity institution, in a collapsed condition and losing blood freely, by a doctor who had been called in and had found her in labour, with the feet of a fœtus of approximately four months presenting. He said that there had been no contraction of the uterus, but expression and traction had been used, and that after the easy removal of the fœtus he had discovered a tear of the cervix extending outwards on the left side. The doctor stated also that he had removed the placenta "with the fingers," and in doing this had found coils of intestine lying in the uterus. Dr. Ford Anderson saw the patient for the first time 14 hours after delivery, when she was still extremely collapsed, and on examination under anæsthesia he found a coil of intestine in the uterus and a transverse rupture 3 to 4 inches long at the fundus, quite independent of the tear of the cervix. Operation was deemed inadvisable in the patient's collapsed condition, so the bowel was replaced under anæsthesia, and, contraction of the lax uterus being stimulated by pressure on the fundus, the uterus was packed with sterilised gauze. Thirty hours afterwards the packing was changed, and 30 hours later the gauze was finally removed. The patient was given pituitrin, morphine, saline solution per rectum, and douches of 1 in 320 lysol, as well as oxygen inhalations. From the first there were swelling and tenderness in the left iliac region, and during the first few days the temperature varied from 103° to 104° F.; the lochia were fœtid. By the eighteenth day the cervical and uterine tears had healed and discharge had almost ceased; pyrexia and evidences of left pelvic cellulitis were still present, when, on the twenty-fifth day, the patient insisted on leaving hospital. A pelvic abscess afterwards had to be opened, but two months later she was completely well.

In Dr. Anderson's opinion convalescence would have been much speedier but for the cervical tear. He said that probably the majority of medical men would hold that in these cases operation offers the best prospect of cure, but it was not considered possible on account of the extremely bad condition of the patient, and the procedure adopted was carried out with but little hope of success. As a result of the present case, and after reading Dr. Herbert Spencer's account in the Obstetrical Society's Transactions for 1900 (Vol. XLII.) of four cases successfully treated by packing with iodoform gauze, Dr. Anderson was inclined to modify his views, and would be interested to know if Dr. Spencer still adheres to the opinion then expressed.

In the course of the discussion on Dr. Ford Anderson's paper Dr. **FLETCHER SHAW** recalled an article in which Dr. W. E. Fothergill had collected a series of cases of ruptured uteri at St. Mary's Hospital, Manchester, and had concluded that in general operation was advisable.

In his reply, Dr. **FORD ANDERSON** read a letter from Dr. Herbert Spencer expressing the opinion that rupture was usually best treated by packing, as the patients were as a rule too ill to stand a hysterectomy.

Dr. **W. FLETCHER SHAW** and Dr. **A. BURROWS** read a paper on

Wertheim's Hysterectomy for Advanced Carcinoma of the Cervix made Possible by the Use of Radium.

Dr. Fletcher Shaw said that the greatest advance hitherto made in the treatment of carcinoma of the cervix was the general adoption of Wertheim's operation in place of the old-fashioned vaginal or pan-hysterectomy. The next great advance was the discovery that radium acted beneficially on the growth. Although on some types of growth and in some situations radium had little effect, in carcinoma of the cervix its action was wonderful.

The first time he had the opportunity of observing this action was in 1914, when an inoperable growth of the cervix with a secondary pelvic mass the size of an orange, in a patient 53 years of age, yielded to radium treatment (three applications) in a remarkable manner. At the end of 12 months there was no growth or mass to be felt; her general condition had greatly improved and she was free from pain, but, unfortunately, the pelvic mass reformed and continued to grow in spite of further applications, and the patient died at the end of the second year. Since that time Dr. Burrows had treated a large number of cases with radium. A large percentage showed a temporary marked improvement, many even complete local disappearance, but in no case of Dr. Fletcher Shaw's had the improvement lasted for more than one year, even with repeated applications. However, the combined treatment by radium and subsequent operation had given good results. In an inoperable case seen by the speaker in November, 1916, the application of radium was advised as a palliative. Three months later, after two applications by Dr. Burrows, the cervix had contracted to little above normal size, had lost all friability, and did not appear to be fixed, so it was decided to attempt operation. The ureters were separated from the adjacent and partly surrounding hard tissue only with the greatest difficulty, since the growth had contracted down under the influence of radium into a smaller mass as hard as cartilage. Dr. Fletcher Shaw had last seen this patient over three years after the operation, and she was then very well, doing all her housework and putting on weight. When he first saw her he did not think she could live one year. Since that date he had operated upon 13 other patients with carcinoma of the cervix too advanced for operation when first seen, but apparently operable two months after the application of radium. In six of the cases he had to abandon the operation owing to the impossibility of separating the ureters or bladder from the hard tissue which had replaced the growth, but in the remaining seven cases he was able to do a complete radical operation.

Dr. Fletcher Shaw then gave details of these cases, all women over 38, of whom five were very well respectively 9 months, 14 months, 19 months, 2¾ years, and 3⅛ years after the operation. Unfortunately all these cases had been done during the war, and several of the specimens had been lost before examination. In case No. 7 no trace of malignant tissue could be found in the cervix, only in one of the glands removed with it. As all the cases were considered inoperable on first examination, the application of radium evidently definitely increased the operability.

Dr. **BURROWS** then read the part of the paper concerned with the methods employed at Manchester in radium treatment and with the estimation of the proportion of inoperable cases of carcinoma of the cervix likely to become operable after this treatment. Much depended upon the technique and the quantities of radium employed. Occasionally cases were rejected because they were too advanced, but their number was relatively small. The main points in treatment were that—

(1) Many tubes must be buried in the cervix and surrounding tissues; and (2) the largest possible dose must be employed. The large number of tubes (five or more) allow a big dose to be given with a minimum of local necrosis. Radium emanation tubes are small in bulk, and when screened by pointed tubes of platinum, the walls of which are 3/10 mm. thick, are easily pushed into place. Other metals are less convenient. Dr. Burrows usually placed a larger central silver screened tube up the cervical canal towards the upper end of the growth. No uniformly good results could, as a rule, be obtained by less than 120 mg. of radium metal, or milleaines of emanation, for 24 hours. Larger doses might be employed and, if

necessary, the time correspondingly reduced. Cautery and curettage were not necessary, but the growth must be cleaned as much as possible *before the treatment* and the part should be douched daily for six weeks after the treatment to prevent the formation of vaginal adhesions Recently Dr. Burrows had treated some cases by Viol's method (*burying and leaving in the cervix small unscreened* emanation tubes), but was not yet disposed to give a definite opinion upon the method, although it appeared to promise even better than the older ones When the question of operation *following radium treatment* had first been considered Dr Burrows was not using the present adequate dosage, but the following details of his first 150 cases in Manchester, the last application of radium to which was given early in 1917, would indicate in some degree the possibilities of increasing the number of operable cases of carcinoma of the cervix by radium

Group (*a*) —One has been well over four years Four have been *well between two and three years*

Group (*b*) —Eight cases were observed for periods of one to two years, during which they remained well but have not recently *reappeared for examination* Four cases similar to the last kept well from six to ten months

Group (*c*) —Thirty four did not return for examination after one treatment This commonly happens because the patients are free of all symptoms and think that they are cured

Group (*d*) —Forty four had signs of disease, but no symptoms for six months or more Five were operated upon by Dr Fletcher Shaw, and two by other surgeons

This gave a total of 102 cases accounted for The remaining 48 cases were benefited *imperfectly or for less periods than six* months, or not at all. Nearly half the cases reported as well at the end of the year in his annual reports recurred subsequently Dr Burrows emphasised the fact that all these cases before radium treatment were regarded as hopeless and inoperable He thought we might safely assume that groups (*a*) and (*b*) became operable, also, perhaps, 10 per cent of group (*d*), 7 of group (*d*) were actually operated upon, making up a total of 28, *or* nearly 20 per cent For the last 2½ years, with improved radium, methods he had been able to report 20 per cent of cases as being well at the end of the year Nearly all of these had clearly become operable in the hands of an experienced surgeon, and if for any special reason a few had not, the number would be more than made up by the improved cases, not included in the 20 per cent , in which the growth, though not completely atrophied, *had sufficiently* receded for operation to be performed. It would thus seem that 20 per cent of inoperable cases of carcinoma of the cervix of the uterus come within the range of surgery after *radium treatment*

Mr. COMYNS BERKELEY congratulated Dr. Fletcher Shaw and Dr. Burrows on their results He had had a large experience of radium treatment, but had found it difficult to follow up cases in London He found that a dose of 250 mg. relieved symptoms, and that the palpable growth disappeared, but the ultimate result was disappointing, as in most cases the growth recurred internally. In one case in which operation had been attempted and abandoned two applications of 250 mg. each had been given, and after two years no trace of growth could be seen, either locally or internally, when the abdomen was opened for the cure of a ventral hernia. Mr Berkeley confirmed the fact that the operation was very difficult after radium. He said that the duration of life after removal of the growth by operation was about three years in any case, so that as yet the effect of the radium was difficult to estimate

Dr. DRUMMOND ROBINSON quoted a satisfactory cure by radium only in a woman of 54, who had refused operation. He said that most of the satisfactory cases reported by the Radium Institute were women past the menopause. He asked for details of time of exposure, and whether Dr. Burrows considered that an expert radiologist only should use the treatment.

Dr. AMAND ROUTH congratulated the authors on such excellent team work. He recalled one case which he had treated at Charing Cross Hospital by a weak tube applied for 20 minutes twice a week —Mr W. GILLIATT asked whether the interval between applications and operation had a bearing on the difficulty of the latter. At the Middlesex Hospital *radium bromide, not the* metal itself, was in use —Mr. GORDON LEY suggested the intraperitoneal application of radium.—Dr. J. P. HEDLEY approved of radium if only as a palliative. On the advice of the Radium Institute he had removed some of the cervix so as to let the emanation get farther in.

In reply to Mr. BERKELEY, Dr. HEDLEY said he had no serious results, though in one or two cases he had had a small fistula or a leak through the bladder or ureter.

Dr. HERBERT WILLIAMSON agreed with Mr. Berkeley's views on the temporary value of radio therapy in these cases. He wondered whether too large doses were being used, and asked about the possibility of using sub lethal *doses sufficient to prevent reproduction* but not to kill the cell. He hoped a collective investigation would be undertaken on the subject.

The PRESIDENT asked Dr. Burrows for his views *on the possibility of harm resulting from radium* treatment

In reply, Dr. FLETCHER SHAW hoped that in time the *operative treatment of carcinoma of the cervix* would be supplanted altogether Concerning the time of interval, he considered that the operation only 24 hours after treatment would be less difficult than after two months

Dr. BURROWS said that radium should be put in and around the cervix and not in the middle of the tissues. He considered that if more than three applications were required the treatment would be a failure The time of exposure was fixed at 24 hours and the dosage was varied in screened treatments Weil, of New York, was using unscreened glass tubes left in the cervix If was difficult for an expert to say that he was *essential, but he deprecated the lack of* standardisation in the treatment used. Dr. Burrows gave various contra indications against the use of radium. A really satisfactory cure was only obtained when no induration was present round the growth. The risk of too early operation was that of sloughing. The therapeutic distance was actually about 1 cm only, and this was an argument *in favour of the use of many tubes* He had had no immediate bad results after the intra abdominal use of radium, and had commonly placed radium tubes adjacent to blood vessels with impunity As to the dangers of radio therapy, he had seen some bad fistulæ, but had also seen terrible results after unsuccessful *Wertheim operations*, and it must be remembered that the cases were considered hopeless to start with In women under 33 or 34 the results were not permanent. The question of sub lethal dosage was entirely theoretical at present

Mr. A. W. BOURNE described a case of

Spontaneous Rupture of the Uterus following Pituitrin

The patient was a 12 para whose last child was born two years ago *Labour started at* 4 A M *on* May *13th*, but pains were sluggish during the day, and in the afternoon a sedative was given on account of primary inertia At 9 P M the os was fully dilated, and the head was bulging the perineum, but as pains *seemed ineffectual* ½ *c cm* of pituitrin was given hypodermically No apparent progress was made till 10 P M , when the pains suddenly became extremely violent Just as the head was being born the patient suddenly gave a sharp cry and collapsed The head receded, pains ceased and the pulse was not perceptible Mr Bourne saw the patient first on admission to St Mary's Hospital, Paddington, at 11 P M , when she was still pulseless and *profoundly shocked*, with very slight hæmorrhage The abdomen was soft, rendering the palpation of the fœtal parts very easy, and fluid dullness rose high in the flanks After an intravenous injection of *gum*, ¼ *gr of morphia, and other restorative measures*, the pulse returned The head was perforated and removed by cutting through the neck It was in the permanent occipito posterior position, but small, and came away with ease, but it was not possible to extract the whole child by gentle traction A further sudden collapse ensued, and in spite of blood transfusion, carried out by Mr C. W G Bryan, the patient did not rally and died at 1 A M The post mortem showed the child's trunk and placenta free in the abdomen, with the uterus retracted behind it, and much free blood There was a tear *of* 7 *inches in the peritoneum of the anterior* leaflet of the broad ligament, opening up the utero vesical pouch anteriorly The rent in the uterine wall was 5 inches long, beginning at the left lateral wall of the lower segment and extending downwards and inwards to involve the cervix The bladder was uninjured

Mr. Bourne considered the case noteworthy on account of the rupture occurring in the absence of any obstruction whatever, after a sluggish and short labour, and when the head was in the act of being born

Dr. WILLIAMSON, Dr. FLETCHER SHAW, and Mr EARDLEY HOLLAND all quoted cases of ruptured uterus without obstruction, following the use of pituitrin before the birth of the child, and emphasised the danger of this procedure

Reviews and Notices of Books.

PELLAGRA.

By H. F. HARRIS, M.D., Atlanta. London and New York: The Macmillan Company. 1919. Pp. 421. 26s.

No one can open this book without being struck by the very large amount of correlated information it contains. It is not so much a record of original work as a résumé of the investigations of others up to recent date. The consistent aim of the author, as expressed in the preface, is to endeavour to state only what the facts seemed to warrant, and in doing so he has been actuated by a desire to arrive at the truth and to aid those who are interested in this most important subject. The historical account of pellagra for which the ancient literature, Spanish, French, and Italian, has been consulted, and especially that of its discovery and spread in the United States of America, is treated more fully than in any other work upon the same subject. It is stated, for instance, that insanity was unknown in the American negroes prior to the Civil War, and, since this race is known to be particularly attacked at the present day, it is assumed that they did not contract pellagra until the "sixties" of the last century.

The author's criticisms of the theories advanced and methods adopted by others are not always tempered with justice. This may be gathered from his scathing remarks upon the Pellagra Commission from this country under the leadership of Dr. L. W. Sambon, which did much to stimulate investigation upon the ætiology in 1910. It would have been acting much more in the spirit of the preface had the author laid stress upon the good work performed rather than drawn attention to the failures of this inquiry. In justice to Dr. Sambon and the late Dr. A. J. Chalmers, the remarks of Babes, of Bucharest, to the effect that "an English Commission, which had probably never before seen pellagra, on arriving in a region where the disease was common, and after seeing the pellagrins, and observing that there was a small gnat which produced a redness on the skin immediately after biting, promptly telegraphed to the world that the insect was the cause of pellagra," might well have been omitted. The same may be said of the strictures upon the work of Stannus upon pellagra in Nyasaland, in which grave doubts upon the correctness of the diagnosis are expressed on the grounds that the description does not tally with the author's own experience. In short, Dr. Harris confesses himself a confirmed zeist, and not open to consider the views of any other school of thought, for otherwise how account for the pseudonym *parapellagra*, in referring to the cases of "pellagra" without maize, described in the British Isles by Sambon, Chalmers, Hammond, Box, and others? Who, with an unbiased mind, after a study of the excellent photographs and paintings of these cases, could doubt that they represented undoubted examples of the disease?

But such being the author's views, it is not surprising that a full chapter is devoted to the history of maize; from this it appears that this cereal was originally an American plant and was given by the New World to the Old. In the year 1632 the first field of maize was planted in Italy, though it did not become a common food until the earlier years of the eighteenth century. The interval between its introduction and the first medical descriptions of the disease would appear to have been a very short one indeed. The possible connexion between the maize theory and the more recent views of protein starvation may be reconciled by the work of Rondoni, who has shown that the adrenals of animals fed on maize contain a much less active secretion than those of normal animals, and that adrenalin possesses the power of correcting the bad effects of a pure maize diet. As a supplement to the maize theory a very full account is given of the fungoid diseases which affect the corn cob, and it is noted that in Colombia a disease known as "pelatina," resulting in loss of hair, teeth, and nails, is due to the ingestion of the maize smut *Uredo maydis*.

The section dealing with the pathological anatomy, and especially the minute changes in the central nervous system, is treated with a wealth of detail; the same may be said to hold good of the account of the symptomatology, to which over 100 pages are devoted. Under the term *parapellagra* or *pseudo-pellagra* are included a number of indefinite conditions, such as alcoholic intoxications, those associated with physiological misery, and pellagra of the insane—dermal alterations in the insane, which have been regarded as of a pellagrous nature, mainly because no other more plausible explanation was forthcoming. The section on treatment is curt, mainly for the reason that good feeding forms the basis of all treatment.

The book contains a complete bibliography of over 1000 references, besides useful appendices dealing with the germination of Indian corn, the Austrian and Italian laws on bad maize, and the eradication of pellagra; it is illustrated by seven plates demonstrating the inflammation of mucous membranes, and the minute changes in the central nervous system. This monograph may be confidently recommended to workers along the indicated lines as sincere, comprehensive, and informatory.

X RAY PUBLICATIONS.

1. RADIOGRAPHY IN THE EXAMINATION OF THE LIVER, GALL-BLADDER, AND BILE-DUCTS. By ROBERT KNOX, M.D. London: William Heinemann. 1920. Pp. 64. 7s. 6d. 2. X RAY OBSERVATIONS FOR FOREIGN BODIES AND THEIR LOCALISATION. By Captain HAROLD C. GAGE, American Red Cross. Same publishers. 1920. Pp. 87. 6s. 3. THE SYSTEMATIC DEVELOPMENT OF X RAY PLATES AND FILMS. By LEHMAN WENDELL, B.Sc., D.D.S., University of Minnesota. London: Henry Kimpton. 1920. Pp. 78. 12s. 4. THE COOLIDGE TUBE: Its Scientific Applications, Medical and Industrial. By H. PILON, of Paris. London: Baillière, Tindall, and Cox. 1920. Pp. 59. 7s. 6d.

1. THIS is an excellent monograph on a difficult branch of radiography that is well worth the study of medical men generally as well as radiologists. It appeared originally as a series of articles in the *Archives of Radiology*, when we had occasion to refer to it, among others, in our periodical comments on that journal. Recent advances in technique have made it possible to gain reliable information from an examination of this region in a quite respectable proportion of cases, and Dr. Knox has rendered a good service in bringing the present position so clearly before us. Beginning with anatomical considerations, the author takes us through the pathology, experimental investigations, radiographic appearances, technique, differential diagnosis, ending with a record of cases and a résumé of the literature and general conclusions. One thing stands out clearly, and that is, that success is more or less directly dependent on powerful apparatus, perfect equipment, and very short exposures. Given these conditions, the X ray examination of this region passes into a new phase, with advantages to all concerned.

2. While the need for rapid and certain localisation of foreign bodies in the tissues is less pressing than it was not long ago, there are doubtless many radiologists and surgeons for whom the subject has a certain amount of fascination. The special feature of the method devised by Captain Gage is the provision of three intersecting lines which join three pairs of marks on the skin, and it is claimed that by these the position of the foreign body is more easily visualised than by any other system. Mechanical aids may be used also, but are seldom if ever necessary, and in his hands, at least, his own method has given an almost unbroken record of successful results. The system is worthy of attention by those interested in this branch of radiography.

3. If the information in this volume upon systematic development of plates was acted upon by those who carry on the dark-room manipulations, it is highly probable that there would be fewer occasions for "repeat" examinations, and, in addition, more com-

plete and satisfactory results altogether There is little doubt that in many instances this very important part of an X ray examination is not treated with the care and attention which are given to the exposure of the plate, and yet careless manipulation in development can nullify the most skilful technique on the part of the radiographer From the fact that this part of the work is often relegated to those whose knowledge of photography is limited, Dr Wendell strongly advocates the use of the tank or stand method of development as giving more certain results and being less influenced by the personal equation There is plenty of room for improvement in this branch of radiographic work, and Dr Wendell's monograph will be a real help in its indicated directions

4 This is a most useful book for all those engaged in the practical use of the X rays The resulting radiation from the Coolidge tube does not differ essentially from that in the older types, but the construction, management, and uses of the tube are so different and its possibilities so much greater, that even yet many of those who use a Coolidge tube for one purpose or another are only partially acquainted with its properties This book answers most, if not all, the questions that arise either within the operator's mind or from outside, and it will do much to popularise still further the use of one of the most important radiological discoveries of recent years The theoretical and practical aspects of the subject are dealt with clearly yet concisely and are well illustrated, drawings and diagrams being used where necessary The all important matter of the adequate protection of the operator receives its full measure of attention

APPLIED ANATOMY AND KINESIOLOGY

Second edition By WILBUR PARDON BOWEN, M S, Professor of Physical Education, Michigan State Normal College Edited by Prof R TAIT MCKENZIE Philadelphia and New York Lea and Febiger 1919 Illustrated Pp 339

LITTLE can be learnt from most of the ordinary text books on anatomy concerning the action of muscles, although without this all other knowledge of them is well nigh useless The object of this volume is to supply practical information as to how the various movements of the body are performed Part I deals with the structure of muscles, their action as levers, and the mechanism of muscular control This is done in the simplest possible manner Parts II and III deal with the upper and lower limb respectively The movements of each joint are first considered, then the muscles controlling the movements are described in turn The origin and insertion are indicated rather than described, the structure occupies but few words, and no mention is made of relations or nerve supply The latter could be added with great advantage, particularly if traced back to the spinal nerve roots Posture, fundamental movements, and gymnastic movements are then dealt with in turn, the muscular action of each being fully described It is a pity, when using Swedish nomenclature, not to adhere more rigidly to the usual order of words "Raising arms forward," for example is a poor substitute for "Double Arm forward raise" The muscle action involved in games and sports affords most entertaining and instructive reading Defects of the foot are fully dealt with, though the essential necessity for training the quadriceps in the treatment of flat foot is overlooked Colin Mackenzie's description of muscle action is mentioned but passed over too lightly, Duchenne's teaching being accepted almost throughout Part IV deals with the muscles of the trunk, with breathing, and with defects of posture Part V describes team work among the muscles, and the muscular action in gymnastics, games, sports, and industrial occupations

The book throughout is well written in an interesting manner It is "applied anatomy" of the muscles, the application is given in essentially practical form, and should be invaluable to all those who propose to take any part in physical education or remedial work The illustrations are numerous and well reproduced It has been a source of regret to many who are interested in the working of the human frame that hitherto so little of interest has been written on the action of muscles Here, more fully than elsewhere, will the reader find food for thought Where else, for instance, will he find the solution to the problem, "What advantage is it to the washer woman to have the tub and board placed below the level of the hips? Above it? What determines the best height for it in any case?" This is a typical question taken from one of the tables of questions which appear at frequent intervals throughout the book

---

JOURNALS

Journal of Industrial Hygiene London and New York Macmillan and Co 21s per annum —A number of articles in recent issues of this journal have dealt with the importance of the social side of industrial medicine Indeed nothing is more remarkable in the pages of this up to date publication than the social tone of its contents, in this respect it differs from other medical journals Nor is it to be wondered at, for nowhere does professional activity come more intimately in touch with the daily life of patients than where the environment of their occupations is in question Social unrest and industrial discontent are to be countered by reduction in labour turnover and prevention of over fatigue This review of the later numbers is in the nature of a running commentary upon the more conspicuous contents

In the December issue Mr C A *Lauffer* points out that there are two classes of health hazard in industry—one concerns each worker personally and the other the general community through the employer In the first class he groups hazards arising from (*a*) poisons, dusts, fumes gases (*b*) heat, humidity ventilation (*c*) lighting, (*d*) crowding and (*e*) accidents In the second (*a*) decreased production, (*b*) labour turnover (*c*) compensation expenditure He points out that medical care started at the factory must extend to the home

> An employee spends only eight or nine hours in industrial service in his home life community and social life during the other 15 or 16 hours of the day he likewise incurs health hazards The superior *lighting heating and ventilating systems installed in* many modern factories make these industrial plants more hygienic from a public health standpoint than the homes movie theatres and churches many of which are more crowded and worse ventilated To be consistent homes boarding houses hotels theatres clubs &c in *which employees spend more hours than in the factory* should be scrutinised and inspected as industrial plants now are in probing sources of health impairment and routes of infection from communicable diseases

The detection of early signs of diminished health and loss of tone can only be carried out through an industrial organisation with an effective clinic

> A worker who is constantly fatigued from any cause or any combination of causes will lose time now and then from sheer exhaustion *The fatigued worker is more susceptible to infectious diseases from* which he makes *a retarded recovery* he becomes more stupid and because less alert he more readily meets with accidental injury from which he recovers slowly since he has impaired vitality and we have injury plus sickness to deal with
>
> It naturally reverts to the *industrial clinic* to find out the *sources of fatigue* to evaluate the *factors* that contribute to the fatigue total and to facilitate the recovery of the individual in the manner indicated by the findings of the inquiry

The case thus set forth is followed up in the same number by Dr C D Selby, who calls for careful physical examination of applicants for work

> The most capable and dependable workmen are those who are healthy physically competent and are assigned to tasks they like and know how to do *rapidly and well* Men working under pleasant conditions void of undue fatigue and hazards to health and limb are the best producers and consequently the best paid are the most contented and valued of employees Industry is now striving to procure such workmen

Dr Selby then proceeds in the light of his own experience at Toledo Ohio, to describe how an initial physical examination should be *conducted* *His method is good and must go far to* reduce *labour turnover* *The same subject is also discussed* in the March issue by Dr Florence Meredith whose—

> examinations were *not for the purpose of turning down anyone* who was fit to work anywhere but were for the purpose of fitting any applicants even the physically handicapped into the work for which they were best adapted physically where they would injure themselves least possibly benefit themselves and continue to work longest *We did not turn down anyone fit to work at all*

She maintains further that "all medical work that is worth doing should *contribute to the sum total of scientific knowledge*" and tells how by a well thought out plan records of work can be classified at a glance Another purpose served is that of educating each worker as to how to maintain health, and for this purpose Dr Meredith holds that familiarity with factory processes is essential The industrial physician has a double duty, one to the applicant for work by warning the unfit and by informing the healthy, the second to society, and here success is lost "if he fails to build into it better units as the result of his work." Ideas on medical examinations are suitably checked by reference to a paper in the January issue by D. R. Kennedy and R. M. Nenstadt, who point out that industrial medicine must not deteriorate into a "society for the prevention of men earning a living," but must concern itself with improving personal hygiene by spreading health knowledge and with medical research.

> "The factories and the schools are the easiest and best centres through which the largest number of citizens can be reached, and therefore become not only the most important strategic point in any campaign of general education, but also the place where responsibility for such education and for remedial work becomes centred. ...... Industry, or rather the industrial organisation, cannot shirk its responsibility in public health save by defying and neglecting its clear duty as an organic constituent member of the public—a group citizen of the community."

Industrial medical service must be established by industry and given a position in each concern worthy of the work which needs the best of physicians and the best that is in them. The scope of work within the factory to maintain the health of an important productive group of citizens is extensive; but the capable physician—

> "will not confine himself to the four walls of his office, or even to the gates of the factory yard. He will, on the other hand, consider his company as but a unit in the community, and will tackle the social problems of the home, the school, and the streets with a realisation of their interdependency."

Two long articles appear in the numbers for February and March from the pen of Dr. Hans Zinsser, who summarises in a useful way the control of infectious diseases; the title adds "in industrial communities," but there is nothing in the articles in question which has a particular industrial bearing, unless we look upon every community to-day as an industrial unit. Nevertheless, the industrial surgeon, engrossed in his own work, will find here information which may be of use to him from time to time.—Quite different is Dr. A. C. Burnham's short but suggestive communication in the issue for May on surgery and increased production. Surgeons have previously taken comparatively little consideration of the element of time in the treatment of injury, or of the element of productive capacity. First, he calls for preventive surgery—i.e., accident prevention—then for skilled treatment at the earliest opportunity; last, for treatment directed to minimise the period of disability and to conserve industrial utility. He points out the need for functional re-education, a branch of surgery which the war has practically invented; and then of vocational education, where previous work cannot be resumed. The rehabilitation of the industrial cripple, who is always with us, is a social duty as important as that of helping the crippled soldier, though, and especially to-day, the element of public gratitude is less apparent. Through the restoration of the worker production may be increased and undeserved poverty decreased.

The journal continues to publish an excellent abstract of current literature dealing with industrial hygiene, which must bring to its readers the growing importance of this branch of medical work. It has now completed its first year of life, commencing a second volume with the May issue. The high standard aimed at has been so far fairly well maintained, but we note a tendency to publish short and somewhat fragmentary articles which do not contain new scientific facts, and at the best can only be looked upon as intended for propaganda.

Journal of the Royal Naval Medical Service. January and April, 1920.—During the war some 20,000 men of the navy became ineffective through disorders of psychology, and to the Naval Medical History of the War, Temporary Surgeon-Lieutenant Thomas Beaton, O.B.E., M.D., has contributed a very valuable paper discussing the nature, treatment, and prevention of their maladies, which were more numerous every year, and always increased most rapidly in summer when the menace of the submarine threatened most. These disorders are, Surgeon-Lieutenant Beaton considers, the outcome of the disturbance of the normal relation between the individual and his environment, and that this may be thoroughly comprehended his paper must be studied. But his analysis is so complete and interesting that it is expedient to attempt a brief summary.

Mental stress, if severe enough, results in disintegration of mind. Mental stress is set up by conflict in the mind, by emotion, or by exhaustion, separate or combined. By conflict; if action must be taken the nature of the action is a matter of choice. Ordinarily such a course is fairly easy, but at sea and in war the inherited, intuitional, and trained impulse to self-protection may have to be ignored, energy will be required to push that impulse aside, and in the mind there will be a persisting unsolved conflict that will cause stress. Emotion, as fear, joy, pity, energises the mind to do something; that emotion may have to be repressed, and in the process the mind may be decomposed. Exhaustion, where there is long-continued conflict or repressed emotion, always comes upon the mind, but it arrives sooner if the person is fatigued or debilitated. Conflict is diminished in the mind by education in conduct—i.e., habit formation—but landsmen joining the navy during war have to make a readjustment too puzzling, too overwhelming for some of them, who in the attempt may go mad. These failures can be prevented by careful selection of recruits of sufficient ability and character, as was attempted later in the war by the American naval physicians, by inciting the recruit to adapt himself, and by showing him how completely the nation's purpose in war is also his own ("propaganda"). Of the men who broke down, 75 per cent. were mentally unstable in their previous lives; we observe what expense might have been saved by employing trained psychologists on the weeding-out. The sailor's life being more monotonous than the soldiers makes mental failures more likely. Disorder of mental function is evidenced by alteration of conduct, and correct conduct can only be defined by comparison with its opposite, which makes a man a bad shipmate or a bad messmate. Good conduct must be chosen as the preferable course by the will of the subject, who is strengthened in his choice by the imminence of disciplinary rewards and punishments. So the mind may be overpowered and the person, who has now become irresponsible, acts automatically—i.e., unconsciously. All people of bad conduct must be removed from the ship; among them are some half-malingerers who get out of the strain a little easily, but if kept on board they become insane, and by their loss the service becomes more efficient. It is not always difficult to detect the malingerer, for he is anxious that his insanity shall be recognised; the real patient insists that he is all right.

The disorders that occur Surgeon-Lieutenant Beaton classifies as the psycho-neuroses in which auto-criticism exists and the patient knows there is something wrong, and the psychoses in which he is not aware of his plight. Their causes are three: actual exhaustion of the organism—the confusional states; persistence of the activity of the defence mechanisms; the anxiety neuroses which are partially readjusted, as in hysteria and shell shock. The degree of stress decides whether breakdown will occur; and Surgeon-Lieutenant Beaton holds that the variety of breakdown depended on the individual. There were some 11,000 cases of what was called neurasthenia, cases without local physical functional disability, not without auto-criticism. The name, in his view, made no imputation of insanity. Ninety-five per cent. were cases of anxiety neurosis, fear for oneself or for others involved with one, and for whom one was responsible. In the navy the incidence was wide; so many men have responsible jobs, small in themselves, yet essential in the functioning of the ship, that consequently men are as prone to develop this neurosis as officers. Officers suffer more in the army in comparison with the men. The anxiety, it was found by Surgeon-Lieutenant Beaton, might be outside the service, in relation perhaps to the family. One per cent. recovered completely and returned to service, 85 per cent. were looked after by friends, only 14 per cent. were certified. Of 100 consecutive cases, it was found that in 50 the thyroid was enlarged; in these and 20 others there were symptoms of hyperthyroidism, and in 30, mostly men above 40, vasomotor disturbances of the class due to disturbed sympathetic innervation.

There were no cases of Graves's disease, but persons predisposed to over-activity of the thyroid were liable to break down under very slight stress. Mental patients recovered in far larger proportion than is usual; this being due to their coming very quickly under treatment. Shell shock was very rare, and only occurred among men in action ashore. The shell-shock syndrome, as Surgeon-Lieutenant Beaton observes, does no good service to a man in action, if on board a ship. Ashore, if he becomes paralysed he drops into cover, and the battle passes away from him and he is protected. At sea he remains in the battle, and paralysis will only prevent him from escaping if the battle goes against his side and his ship sinks. Shell shock is not a protective but a destructive syndrome afloat, so it did not occur. The mental health of the service, he says, rests in the hands of the executive officers. The "happy ship" has little crime and few mental breakdowns. "Fortunately, many naval officers become practical psychologists," and are able to get their men's confidence and make them efficient.

This article of Surgeon-Lieutenant Beaton's, if read and understood by the service in peace-time, should help to diminish the mental breakdowns of the next war. He has put his service as a temporary officer in the navy to good use, and his description of the severity of service in the Fleet will make every reader more grateful than before to the splendid service which stood the strain and saved us.

LITERARY INTELLIGENCE.—Mr. William Heinemann announces the approaching publication of "Venereal Diseases, their Clinical Aspect and Treatment," by J. E. R. McDonagh.

THE LANCET.

LONDON: SATURDAY, JUNE 12, 1920.

The People Desire to be Deceived.

THE parting by the public with money to specious advertisers who promise to cure disease or otherwise to promote the health of their clients, is a world-wide and world-long happening, to the eternal puzzledom of medicine. But in the United States of America the Government empowers itself to stop the trade of the vendor of fraudulent nostrums in certain directions. To the extent that it does so America is advancing civilisation. The action taken in the United States during the past few years is summarised in a booklet issued by the American Medical Association, entitled "Medical Mail Order Frauds," a title which more or less explains itself, and which details methods so familiar to our readers that only the briefest recapitulation of them is called for. The medical mail order business is initiated by advertisement, in response to which persons affected, or believing themselves to be affected, by disease write to the advertiser. In reply a form is sent to them, which they return filled up with details of their symptoms as observed by themselves. Particulars of proposed treatment and demands for payment follow in due course from the proprietors of the nostrum, the suggestion, implied or expressed in some of the correspondence or advertisements, being that the treatment represents the considered conclusion of a medical man. In a particular case described in "Medical Mail Order Frauds," instead of the letters being submitted to the discriminating physician—who, if he exists, may or may not be discriminating, but must have vague notions of ethics—they were passed on to girl clerks, who answered them from a book of models, or, as lawyers might call them, "common forms," furnished by their employers. Business was accelerated by division of labour, one girl underlining material passages and another picking out from the book of models such replies as to her might seem appropriate to the symptoms indicated by her colleague. Of course, if such a business enterprise as this is permitted to be carried on without interference, the manager of the institution who thus battens on the infirmities of his fellows is hardly to be blamed if, as success inflates him, he conducts his work through clerks instead of defrauding his customers personally. The trade is shown in "Medical Mail Order Frauds" to have been worth many hundreds of thousands of dollars yearly to its businesslike organisers.

This particular "business" and others of a similar nature are, we presume, now wiped out so far as traffic in the United States is concerned, for in each case given in the pamphlet we are informed that a "fraud order" was issued. In connexion with the "fraud order" a further order "denying the use of the mails" is made, apparently either as a necessary accompaniment of the first order, or as an addition rendering it more effective. The Post Office in America appears to be the prime mover in prosecutions where the use of the mails to assist in the fleecing of the public is an essential feature of the trade. The American Medical Association emphatically praises the efficient service of the United States postal authorities in protecting the public against "mail order medical fakers." It adds that this has often been done in the teeth of adverse political influences set in motion by the wealthy "fakers," and it highly commends the postal inspectors who have carried out the necessary investigations. This fact may be brought to the notice of our Postmaster-General with hope of imitation. For American virtues may damage this country seriously unless we in our turn become virtuous. A "fraud order" and "denial of the mails" may stamp out a dishonest and mischievous trade in the United States, but it will not prevent that trade from enjoying prosperity overseas. We have our own "mail order medical fakers," and there is nothing, so far as we are aware, to prevent enterprising Americans from adding theirs to ours. With the majority of the names of commodities given in "Medical Mail Order Frauds" we are not familiar, or have only observed them in the advertisements of American publications of an inferior type sold in this country. One name, however, is that of a commodity which, banned in the United States as fraudulent, is advertised with impunity in the United Kingdom. The exploiters of "sargol" are described by the American Medical Association as having been found guilty of fraud in America and fined $30,000, after promising that their business should be discontinued. The fine was paid and on Feb. 27th, 1917, the Post Office Department issued a "fraud order" against the Sargol Company denying it the use of the mails.

But we find in our newspapers, some of them important and highly respected, advertisements of sargol during the month of May, 1920. The advertisements are similar in form and illustrative matter to those reproduced in "Medical Mail Order Frauds," and we give them gratuitous publicity. Under the headline, "How to Become Plump, Popular, and Attractive," they commence with the inquiry—

> "Would a little more flesh make you more stylish and attractive? Would 10 or 20 pounds more make you better satisfied with your personal appearance? If so you should try Sargol. It will make you nice and plump, give you greater strength, better health, and double your powers of endurance."

The evidence given in America was to the effect that sargol as sold there was made in accordance with a formula devised after a short consultation between one of the promoters of the business and a man connected with the "private formula" department of a famous firm of pharmaceutical chemists. Sargol was made up by that firm at a price from 53 to 78 cents per 1000 tablets, and sold at the rate of $25 a thousand, its composition being: Extract saw palmetto, 2 gr.; hypophosphite calcium, ½ gr.; hypophosphite sodium, ¼ gr.; hypophosphite potassium, ¼ gr.; lecithin, ⅛ gr.; extract nux vomica, 1/12 gr. And that is the composition on which the public is invited to grow nice and plump and strong. Some of the constituents of sargol under that formula may be in some degree tonic, but none of them consumed singly or in combination could affect the weight of the thin or emaciated, without reference to the cause of their condition, or in the manner claimed by the advertisers.

On the question of whether the public should be protected generally from robbery by greedy advertisers who promise more than they can perform, we say nothing. With the designs even of fraudulent traders, so long as they only affect the purses of the credulous, we are not concerned. When, however, such persons pretend to cure disease, or to promote health by means which cannot achieve either purpose, we consider it our duty, in the interest of the health as well as of the pockets of the public, to call attention to the nature of the business. More particularly are we interested when the claims of the advertiser are supported by testimonials and recommendations alleged to have been given by members of the medical profession.

◆

The Clinical Diagnosis of Exudations in the Throat.

QUITE apart from its convenience, the establishment of any reliable diagnostic indications obtainable from a simple examination of the fauces, as opposed to a bacteriological examination in the diagnosis of different forms of throat illness, is welcome, inasmuch as it implies a more exact knowledge of disease. The amount of time, too, which may be saved by making a diagnosis from ocular inspection on the spot rather than by awaiting for the result of a bacteriological examination may, as is rightly emphasised by Dr. H. DRINKWATER in an article on the clinical diagnosis of diphtheria and other exudations in the throat, which appeared in THE LANCET of May 29th, make just the difference between life and death if treatment be delayed until the report from the laboratory is received. Unfortunately, this is a practice which is too often followed, occasionally, in cases of diphtheria, with disastrous results, as is also the not uncommon mistake of ignoring positive clinical evidence, even when fairly patent, in view of a negative bacteriological finding.

Admitting the paramount importance of immediate clinical evidence, the whole question hinges on its reliability. As a correspondent suggests in another column, it seems too good to be true. Dr. DRINKWATER, in the article referred to, lays down certain data concerned with the naked-eye appearance of the fauces by which he claims that he can invariably differentiate between diphtheria and Vincent's angina, on the one hand, and other forms of sore-throat showing exudation, of which he instances follicular tonsillitis and influenza. Dr. DRINKWATER bases his claim upon an experience of over three years in a fever hospital serving the needs of a population of 80,000, in the course of which he states that in every instance his naked-eye diagnosis was confirmed by subsequent bacteriological examination. If this be so, Dr. DRINKWATER is to be sincerely congratulated, for we doubt if it can have fallen to the lot of many other observers, even if possessed of an equally wide experience of exudation throats, to have been so uniformly successful. The article is illustrated by a number of drawings which, allowing for an inevitable loss of definition incidental to their reproduction in print, serve to bring out the special distinctions on which Dr. DRINKWATER relies. The main proposition which emerges on careful perusal of the article is that on no single one of the six areas into which, for the purposes of clinical description, the author divides up the fauces, will more than one patch of exudate be seen in the case of either diphtheria or Vincent's angina, and that if there be more than one the diagnosis of both of these two affections is negatived. At this somewhat sweeping statement we confess to a feeling of some surprise. Dr. KNYVETT GORDON, in a letter we published in our issue of June 5th, states that it is by no means uncommon in adults for diphtheritic exudation to commence at several points on the same tonsil, and thus closely simulate follicular tonsillitis in appearance. That diphtheria and Vincent's angina, moreover, should stand alone in presenting a single patch on the tonsillar area is hardly, we think, in accord with the experience of most observers. In follicular tonsillitis, it is true, the spots or patches are usually multiple, but cases are surely not uncommon in which a single patch is present on the tonsil and which as the result of bacteriological examination are classed as "coccal." These are the very cases which, though neither diphtheria nor Vincent's angina, are apt to so closely simulate the former as to give rise to difficulty in diagnosis. This form of throat, too, is sometimes met with in scarlet fever, the patch being usually confined to the tonsillar area. Dr. DRINKWATER admits that this peculiarity of distribution of the patches affords no guide to the differentiation of diphtheria from Vincent's angina, though he describes certain distinctive appearances in each of these affections which should prove helpful in diagnosis.

The special characteristics of the exudation which Dr. DRINKWATER regards as distinctive of diphtheria are the following: (1) It is raised above the level of the mucous membrane; (2) the edges of the deposit are sharply defined all round; (3) in colour it may be white and glistening, bluish, yellow, or spotted with black or red. Most observers, we think, will agree with the writer as regards the first and the last of these indications, but that the exudate is always sharply defined in its entire circumference we cannot agree, although this feature is very noticeable in the specimens of diphtheritic exudation (Figs. 2 to 7) depicted in the illustrations. It is by no means an uncommon experience in some of the worst cases of faucial diphtheria, especially when the palate is involved, to see the exudation merging into the pallid and œdematous mucous membrane without any line of demarcation whatever between them. We note with some surprise that Dr. DRINKWATER makes no distinction between an exudation associated with the Hoffmann bacillus and one in which the Klebs-Löffler organism is present. He classifies them both as diphtheria. The characteristic appearances of Vincent's angina are well described and should prove very helpful in diagnosis. The illustrations, too, bring out very clearly the points on which Dr. DRINKWATER relies, especially the longitudinal sulcus (Fig. 8) and the fading off of the lower margin of the patch (Figs. 9 and 10), an appearance which, by the way, is sometimes seen in secondary syphilis. It might be added that the characteristic lesion of Vincent's angina is, on the whole, more apt to suggest an ulceration rather than a true exudation, another point in which it resembles syphilis. Dr. DRINKWATER'S article is deserving of careful study by anyone engaged in general practice, for even if one is not prepared to go the whole way with him and accept his propositions as infallible there is much in his teaching to inspire confidence in the clinical diagnosis of throat affections in circumstances where time is a matter of importance.

A Great Appreciation.

The dinner in appreciation of the services of the Royal Army Medical Corps and of the civilian officers attached to it during the war, a short account of which appears elsewhere, was an extraordinary recognition, spontaneous, unexpected, and generous, of the medical work throughout five terrible years —work, it should be added, which still remains in active doing in every direction. It was, as Sir Alfred Keogh said in his eloquent reply to the words of national thanks uttered by Lord Midleton, Mr. Churchill, and Earl Haig, an outward sign that 60 years of hope and endeavour had at last reached fruition. For to-day, while the medical officers of the army have become, in every sense of the words, an integral part of all military plans and designs, they are also enabled to preserve close association with their civilian brethren.

The bitter lessons learnt in the Crimean War, 60 years ago, were mostly neglected, were greatly relearnt in the South African War, and through the events of the world war have become the accepted wisdom of advanced communities. When Sidney Herbert determined to ensure, during a later tenure of office, that the misfortunes which overtook our army in Russia, with its miserable absence of medical equipment, its total neglect of elementary hygiene, and its lack of nursing material, he and Florence Nightingale began what it has been left to the statesmanship and science of the twentieth century to transform into ordered being. It was at Sidney Herbert's suggestion that four supplementary commissions were instituted in connexion with the Royal Commission on the Sanitary Condition of the Army, which was made necessary by the Crimean disasters. These commissions dealt with the construction and sanitation of hospitals and barracks, with the condition of the Army Medical Department—for which Herbert drafted a code of regulations, with the right keeping of army statistics, and with the provision of facilities for the proper education of the department. The ideals which Herbert placed before himself are those which the Directors-General of the Army Medical Department, notably Sir Alfred Keogh and his successor Sir John Goodwin, have kept steadily before them, but it is not anything for this country to boast of that during the period of exactly 60 years, which elapsed between the opening of the Great War and the close of the Crimean War nothing was done worth doing, until the South African War again found us unready. We are not unmindful, however, in saying this, that medicine, preventive and curative, had vastly more to give, with all the Listerian doctrines behind it, than it could have given until the closing phases of the Victorian epoch. But the dinner to the Royal Army Medical Corps, at which the hosts included the principal statesmen and men of affairs who have presided over the War Office in recent times not only was a tribute of praise excellently directed, but a public pledge that for all future time no one will doubt that well-administered preventive and clinical medicine will win wars.

Honour to General Gorgas.—In the course of a visit to the Queen Alexandra Hospital at Millbank on June 8th His Majesty the King bestowed the K.C.M.G. on Surgeon-General W. C. Gorgas, of the American Medical Service.

Annotations.

"Ne quid nimis."

THE BIRTHDAY HONOURS.

The Birthday Honours published last Saturday contained many names, and the notes which have appeared in the daily press upon the services rendered by those selected for notice show very well how various were the activities concerned throughout the war and the high level of accomplishment reached by many sections of the community. The members of the medical profession selected for honour include the following: Dr. James Dundas Grant, the well-known aurist, Mr. Arnold Lawson, who has done admirable ophthalmological work at St. Dunstan's, and Colonel William Taylor, formerly President of the Royal College of Surgeons in Ireland, receive the K.B.E. The honour of civil knighthood has been conferred upon Dr. Sidney Robert Alexander, many times Mayor of Faversham, Professor Frederick William Andrewes, F.R.S., pathologist to St. Bartholomew's Hospital, whose work in medical research is known to us all, Dr. Sydney Beauchamp, Dr. Charles O'Brien Harding, and Colonel Hormasjee Eduljee Banatvala, I.M.S. (ret.), who was lately Inspector-General of Civil Hospitals at Assam. Dr. Beauchamp was medical adviser to the British Delegation at the Peace Conference, and the post was no sinecure during the epidemic of influenza. He was responsible for the organisation of Wrest Park as a military hospital in September, 1914, and was its chief medical officer till its destruction by fire in 1916. Dr. Harding has been five times Mayor of Eastbourne, and recently received a presentation from the inhabitants in recognition of the impartiality, dignity, and efficiency with which he performed his onerous duties. Surgeon-Rear-Admiral George Albert Dreaper has been awarded the C.B. The Kaisar-i-Hind Medal has been bestowed upon Shamrao Ramrao Moolgavkar, principal medical officer to the Bikaner State, and Miss Millicent Webb, the lady-superintendent of the Dufferin Victoria Hospital in Calcutta. The Imperial Service Order of India has been bestowed upon Mahendra Nath Bhattacharji, personal assistant to the surgeon to the Governor of Bengal, and Egambaram Rangaswami Doss, the late chief attendant to the Medical College in Madras, has received the Imperial Service medal. The British war service has been recognised by the President of the French Republic in the persons of Sir Arthur Staley, chairman of the British Red Cross Society, who becomes a Commander of the Legion of Honour, Sir George Beatson and Dr. Alexander Granville, the British Red Cross Commissioner at Alexandria, who have been made Officers, and Dr. Septimus Sunderland, who has been made a Chevalier of the same Order. The last honour is also conferred upon Miss Edith Pye, the directress of the Friends' Lying-in Hospital at Châlons. Dr. Alexander Granville has also had conferred upon him the Order of the Crown of Italy. The King of Greece and the President of the Chinese Republic have conferred upon Sir William Robert Smith, late Sheriff of the City of London, a Commandership of the Order of George I. and a Second Class with Grand Cordon of the Order of the Excellent Crop respectively.

Medical men will very well recognise the appropriateness also of the following distinctions:

Mr. Wemyss Grant Wilson, director of the Borstal Association and of the Central Association for the Aid of Discharged Convicts, has received the honour of knighthood. Mr. C. M. Hutchinson, the Imperial Agricultural Bacteriologist, and Mr. R. S. Pearson, Forest Economist at the Research Institute of Dehra Dun, have received the C.I.E.

THE STANDARDISATION OF TREATMENT BY RADIUM.

To form an accurate conception of the value of radium in the treatment of malignant disease it is necessary to have some standards by which ideas can be fixed and comparisons made. In the course of the discussion at the Section of Obstetrics and Gynæcology of the Royal Society of Medicine, reported on p. 1270 of our present issue, various speakers gave hopeful or guarded opinions as the result of their experiences, but it was difficult to extract much helpful information owing to the lack of uniformity in the methods used and to the lack of precision in differentiating these methods. Thus, some used one tube of radium only and some many tubes. Quantities varied between 25 and 250 mg. of radium. The applications were given daily by some, weekly by others, and at periods of six weeks by a third set of investigators. The duration of exposure varied from 20 minutes to two days. Metals of known and unknown nature and thickness were employed as screens, and in some cases results investigated only a few days after the treatment, the question of a radium reaction being left out of consideration. While some buried tubes in the growth, others were content to place them against its surface. If progress is to be made along this hopeful line of treatment the operator must form a clear conception of what he is doing, and why he is doing it; of the changes likely to occur and the approximate time of their development. For purposes of collective investigation some standardisation of methods is essential. This does not imply absolute fixity or any unreasonable attempt to limit such variations as seem desirable; but it does imply persistence in a defined method over at least one series of cases, with subsequent alteration only for scientific reasons or as a result of definite observations deduced from that series. A clear statement of the exact technique used in treatment would enable one worker in radium to obtain valuable help from others. In England a helpful step in this direction would be the adoption of the practice of describing all quantities of radium used in terms of radium element or metal. It is the element itself, with its decomposition products, that is the source of the radiations, and physicists are strongly of opinion that radium element is the proper scientific standard. The use of radium bromide ($RaBr_2 2H_2O$) as a standard is merely a survival of the older commercial methods of selling radium salts, and leads to endless confusion at meetings and in medical literature. There is no reason why its use should not die out, as did the older method of describing the strength of radium plates by their activity in relationship to uranium. The change would be very easy, as the quantities of salt to metal used are approximately as 2 to 1. Another point is that the unit of radium emanation is the "Curie"—that is to say, a Curie is the quantity of emanation in equilibrium with a gramme of radium element. Thus, so far as medicine is concerned, to talk of a millicurie of emanation is equivalent to talking of a milligramme of radium element. The bromide standard obviously introduces an unnecessary complication, and, moreover, the exclusive use of the radium element unit would bring us into conformity with the big American radium centres.

ANÆSTHETISTS IN AMERICA.

THE American Association of Anæsthetists at a recent convention passed some resolutions which are very interesting to all concerned with anæsthetics. It will be remembered that not long ago we printed several letters from correspondents who discussed the advisability of encouraging the administration of anæsthetics by nurses. This practice, which necessity compelled during the war, and which as an emergency measure fulfilled its purpose admirably in most instances, has no wide measure of support in this country. In America it is more common, and the Association of Anæsthetists points out its disadvantages and those that accrue still more forcibly if administration is entrusted to unqualified persons even less instructed than the nurse. The Association expresses itself as "unalterably opposed to the employment of lay anæsthetists, nurse anæsthetists, and all other types of anæsthetists who shall not have graduated from recognised medical or dental colleges and have been licensed to practise medicine or dentistry." We are in cordial agreement, as we fancy will be our readers, with the opinions of the American Association of Anæsthetists, and hope to see its opinion supported by legal enactment in the chief States.

STRICTURE OF THE ŒSOPHAGUS.

CICATRICIAL stricture of the œsophagus, resulting from the swallowing of caustic fluids, is fortunately not very common, for, when the stricture is multiple or extreme, treatment is by no means easy. Gradual dilatation by the passage of increasingly large bougies is a difficult and tedious business, and very trying to a nervous patient. Moreover, it is not possible to control the movements of any but the finest bougie by means of œsophagoscopy. Surgical intervention by the thoracic route has been essayed, but gives a high rate of mortality. Dr. Charles Goris has recently published[1] a series of nine cases treated by surgical intervention through the stomach. The operation is carried out in two stages. In the first a gastro-fixation is performed, a large area of the cardiac end of the stomach being exposed. For the second stage of gastrostomy no anæsthesia is required, except in the case of children and nervous adults, the incision of the stomach wall being quite painless. The usual local anæsthesia is, of course, necessary for the contemporary passage of the œsophagoscope. A fine bougie is then passed into the stomach and a cotton thread attached and drawn through the stricture—cotton being preferred to silk since it is more resistant to digestion by the gastric secretion. An endless thread is thus established to which "olives" of increasing size may be fastened and an easy method of dilatation established. Once started, the patient soon learns to pass bougies for himself, and cure is comparatively rapid. Eight of Dr. Goris's cases were completely successful. In the ninth case it was found impossible to pass a bougie without internal œsophagotomy. A temporary recovery was made and olives passed, but the patient was unable to continue to swallow on account of the pain caused. It was shown by radiography that a false passage had been made by the œsophagotomy.

"GRADE 'A' CERTIFIED MILK."

MILK bearing this description is now being retailed in Manchester, put up in sealed one-pint bottles at a cost of *7d.* per pint—that is, *3d.* a pint dearer than the milk usually supplied for domestic purposes. The milk comes from the farms direct in the natural raw condition, accompanied by a Government guarantee of purity, and is neither pasteurised nor sterilised. The cattle must have passed the tuberculin test, and the buildings and utensils have to be certified by the Ministry of Food as conforming to their required exacting standards of cleanliness. To safeguard the public against the substitution of old milk the date on which the milk was bottled and sealed at the farm is stamped on the outer label. The milk appears to be bought chiefly by those who have charge of young children, and it would be an interesting experiment, in view of the approaching hot weather, to subsidise some of the poorer families attending welfare centres to enable them to use this milk, in the attempt to estimate the extent to which clean milk would prevent summer diarrhœa in infants.

NORMAL HORSE SERUM IN SEPSIS.

IN the *Journal of the Royal Army Medical Corps* for April Dr. E. Emrys-Roberts gives an account of the use of normal horse serum inoculation in the treatment of sepsis in war wounds. Two classes of case are recorded by Dr. Emrys-Roberts: one a group of three cases of acutely spreading gas gangrene at a casualty clearing station, the other a group of 14 cases of serious wounds, with swinging temperatures, undergoing treatment at the Queen Mary's Military Hospital, Whalley, Lancashire. Neither septicæmia nor secondary hæmorrhage was held to be a contra-indication, but cases with "pocketing" or sequestrum formation were excluded as far as possible. In all the cases recorded encouraging results were obtained, with reduction of temperature, disappearance of slough from wounds, and ultimate recovery. Normal horse serum has, of course, been used in the treatment of various acute and chronic infective diseases for a number of years. It has also been used for hæmoptysis, hæmophilia and secondary hæmorrhage. In most cases the doses employed have been small—e.g., 5–10 c.cm. Dr. Emrys-Roberts, however, used massive doses, beginning with 50 c.cm. and increasing up to 150 c.cm. The question of dosage, therefore, may be a matter of importance, and may partially explain why Dr. Emrys-Roberts's cases did so much better than cases previously reported in civilian practice. We are inclined to think, also, that some allowance must be made for the character of the cases—the young healthy adult in excellent physical condition is probably a better subject from the point of view of resistance to sepsis than the weakly town-dwelling civilian of ordinary hospital practice. But in any case the results are so exceptionally good that we hope extended trial of the method will be made; and that, furthermore, care will be taken in the choice of suitable cases. New methods of treatment are often unjustifiably condemned because they will not cure everything from migraine to carcinoma. With regard to the interpretation of the good results which he obtained, Dr. Emrys-Roberts is inclined to seek an explanation in the complement-content of the normal horse serum. Possibly this question might be cleared up by the use of decomplementised serum. If increased complement-content is in some way at the bottom of this treatment, then, as Dr. Emrys-Roberts points out, questions of leucocytic activity, cellular reaction, and antibody formation will have to be explored to this end. It is interesting to note that inoculations of peptone, bacterial protein (i.e., vaccines), and numerous other non-specific protein substances, appear to possess the power of reducing pyrexia in certain cases of chronic infective diseases, such as tuberculosis and chronic sepsis. Here is a difficult though fascinating field of research. Numerous cognate questions in serological and bacterial therapeutics seem to suggest that we are possibly on the verge of interesting new light on the old question of the relation of metabolism to temperature and antibody production.

THE SPAS OF SPAIN.

WE have received from a correspondent some notes about the spas of Spain, which are regretably little known in the British Isles. The mineral waters of Spain are of great number and variety, rich in medicinal properties, and are much favoured by Spaniards themselves. Some of the more accessible of these health resorts are likely in the near future to be visited by those tourists who used to frequent German and Austrian spas.

To many accustomed to the extraneous luxuries and amusements of spa life in other countries, Spanish health resorts may appear somewhat dull. The hotels often supply but little beyond the essential services of board and lodging. A band is by no means a matter of course, even in a fairly large establishment. The spas are private properties, licensed by the State only after a thorough investigation and analysis of the medicinal properties of the water in the springs. Many of them are run by a limited liability company and are advertised extensively. The advertisements do not err on the side of moderation; some spas appear to be "cure-alls," and among the "indications" given for the waters, no organ of the body or vague symptom of disease is left out. There are no municipal spas. Unlike the watering-places in other countries, no one can take the waters without consulting the official doctor of the establishment, who is a member of the Association of Mineral Water Doctors and holds his appointment as a specialist.

There are over 200 spas in Spain, scattered broadcast throughout the peninsula. Some of these resorts are of the most primitive character. In general, however, the arrangements are sufficiently convenient for ordinary people who desire to take their cure seriously and are content to lead a simple life and enjoy a delightful climate among a friendly and polite people. The difficulties for travellers in Spain are mainly those of the railways, but in certain parts these have greatly improved in recent times. In Spain "a cure" is a very popular holiday. A few weeks at an inland watering-place compares with an Englishman's trip to the sea. Some of the best known resorts are situated amid beautiful surroundings, and are within easy reach of interesting places. As a rule the season lasts from the beginning or middle of June to the end of September. For convenient travelling it would be necessary to confine the list of places to those within easy range of San Sebastian and Santander, and a useful variety of waters can be obtained in these districts. The following are among the best known, and in general the arrangements are on more or less up-to-date lines.

Alzola.—Saline and gaseous, with an appreciable amount of lithia; suitable in dyspepsia, gout, and rheumatism, situated in beautiful surroundings. Several hotels beside the establishment with 80 bedrooms. In the Balneario every kind of apparatus for hydropathic treatment.

Caldas de Besaya.—Thermal saline, not far from Santander. Approached from San Sebastian. Useful in rheumatism.

Cestona.—Thermal saline, sulphated alkaline with a trace of lithia, used in diseases of liver and digestion, in gout and rheumatism. Fine bath installation, Zander, &c. Station Arrona on San Sebastian-Bilbao line.

Fuencaliente.—Mild ferruginous alkaline waters, useful in debility. On San Sebastian-Madrid line, near Miranda.

Lierganes.—"Gypsum waters" in chronic catarrh and in skin diseases. Near Santander from San Sebastian.

Molinar de Carranzas.—Saline and gaseous, radio-active, indicated in rheumatic affections. Not far from Bilbao, on the line to Santander.

Ontaneda.—Thermal sulphur waters, similar to those of Harrogate; near Santander, on Bilbao-Santander line.

Sobron Y Sorportilla.—Alkaline waters, indicated in rheumatism and dyspeptic troubles. Situated on the Ebro, near Miranda.

Solares.—Alkaline water, situated in beautiful scenery and within easy distance of interesting places. Near Santander.

Zaldiva.—Strong sulphur waters. A quiet little spa, situated in a small park near Bilbao. Good bath installation; on San Sebastian-Bilbao line.

The above resorts are all easily approached from San Sebastian and form samples of Spanish spas; pamphlets, with fuller details of their attractions, can be had from their respective directors. It is to be hoped that continental travel will soon become less complicated by passport formalities, as the interchange of visits between the people of neighbouring countries is more likely to cement national friendship than formal visits by their rulers. The insular attitude of the British was passing peacefully away, under the influence of cheap tours abroad, when in 1914 the whole of continental society was turned upside down and inside out by the war. That attitude should not return, but it will remain alive until habitual continental travel can be re-established among the middle classes. The present generation will hardly care to fraternise with the German-speaking people, but Spain is such an old enemy as to have been for many years a valued friend.

TUBERCULOSIS IN A REMOTE COMMUNITY.

IN the current number of *Tubercle* Dr. E. Björn-Hansen records a series of observations on the incidence of tuberculosis in a Norwegian mountain village in which no death from tubercle has been known. There is no road to the village, and the mother-parish is 14 miles distant. The folk are farmers, and number 53; the children go to the village school and are thus isolated from the outer world till they are prepared for confirmation in the mother-parish, apparently at the age of 15. It is thus not surprising to find that all the 17 children under that age were tubercle-free, as indicated by a negative von Pirquet reaction. Among persons from 16 to 25, 40 per cent. showed a positive reaction and, as might be expected, advancing ages revealed an increasing percentage of positive results, but there is again a fall at ages above 45, doubtless due to the fact that even in the mother-parish there was hardly a case of tuberculosis before the late "seventies" and that the whole district was then still more isolated than now. Of actual clinical tuberculosis 3 cases are noted. First, a consumptive labourer lived on one of the farms 18 or 20 years ago for 3 years, and in this and a neighbouring farm which he frequently visited all the adults, but none of the children, gave positive reactions. The second case is that of a young man who suffers from benign tubercle of the lungs contracted while at work elsewhere and only recently returned, while the third case is one of non-suppurating disease of the glands. Dr. Björn-Hansen considers that all cases giving a positive reaction are derived from contact with the first of these three cases, or are newcomers, or are those who work much elsewhere, and he attributes the fact that tuberculosis has not been more virulent in this virgin soil to "the small quantity of infectious matter, the rare opportunity of re-infection, or the healthy life on these mountain farms." It should be added that the veterinary surgeon knows of no tuberculosis among the cattle, but no tuberculin tests have been applied.

THE SYSTEMATIC CONSERVATION OF MUTILATED FINGERS.

IN the *Gazette des Hôpitaux* of April 27th M. Paul Bonnet has called attention to the importance of systematic conservation of mutilated fingers the function of which is definitely lost, with a view to their use in plastic operations. During the war the premature or unexpected explosion of hand grenades rendered us familiar with such lesions. The treatment found necessary for conserving as much function as possible furnishes details of technique which may be useful in industrial accidents. M. Bonnet insists on the need of being as parsimonious as possible with regard to removal of skin and of delaying amputations which may appear necessary at first because the use of fingers seems to be irremediably lost. The skin of fingers which it is decided to sacrifice may afterwards prove useful in plastic operations necessary for loss of substance of the palm. M. Bonnet reports the following example.

A shoemaker, aged 43 years, was wounded by fragments of a grenade on August 27th, 1916, and brought to a field hospital four hours later. In addition to other wounds, there was a large irregular wound of the left palm extending slightly on the dorsum of the hand. The superficial palmar vessels were torn, and the tendons of the middle and ring fingers were divided. The ring finger was torn off from the middle of the first phalanx. The third phalanx of the middle finger with its integument was blown away, and the base of the finger was involved in the palmar wound. The first phalanx was fractured, and the flexor tendons were divided, but the finger was still attached to the hand by the skin of its dorsum. The superficial palmar arch and two collateral vessels were wounded and were ligatured. Dead tissue was removed from the margins of the wound. The function of the middle finger was irremediably lost because the first phalanx was the seat of comminuted fracture and the flexor tendons were divided, but sufficient integument remained for the nutrition of the finger. The wound was cleansed with Dakin's fluid, and then carbolic solution was applied and a dressing impregnated with iodised alcohol. On Sept. 14th the aspect of the wound seemed to be favourable for a plastic operation. The wound was painted with tincture of iodine and freshened over its whole surface by curetting exuberant granulations. The margins, which showed a few points of sloughing, were freshened with a bistoury and in places undermined so as to allow the skin to be drawn over the wound, which was too large to be covered by the digital flap alone. The middle finger was divided longitudinally on its palmar surface, and then boned and freed from its tendons, the skin only being preserved. This constituted a large flap, connected to the dorsum of the hand by a pedicle 3 cm. broad. It was decided to preserve the stumps of the first phalanges of the middle and ring fingers in the hope that they might help in prehension. The bone was freshened by division with forceps, and a stump 1 cm. long thus preserved. The flap derived from the middle finger had then to cover the stumps of the first phalanges of the middle and ring fingers, over which it was reflected, an extensive surface of the palm, and a small surface of the dorsum of the hand. It could not do this completely; there remained at the upper part of the palmar wound a small quadrilateral surface uncovered. Healing took place in a short time, but the patient was not able to resume his occupation of shoemaker, and the finger-stumps did not appear to assist in prehension. The results of the autoplasty, however, were excellent.

This method of cheiroplasty by "boning a finger" was practised before the war, and described at the Société de Médecine de Nancy in 1911 by Gross.

DIABETES AND INFLUENZA.

According to Dr. Ketil Motzfeldt,[1] of Christiania, though numerous cases of diabetes were published in connexion with the influenza epidemic of 1890, only a few instances of this association have been recorded during the last epidemic. He reports four cases in which the first symptoms of diabetes set in during an ordinary attack of influenza or shortly afterwards. In spite of the youth of the patients, who were aged 14, 15, 20, and 35 years respectively, the diabetes was of a very mild character, and in three cases the tolerance for carbohydrates increased considerably during the treatment. The first case was of special interest, inasmuch as the possibility of a pancreatic infection was suggested. The patient, a man aged 35, began to suffer from a peculiar deep-seated pain in the epigastrium during the first few days of his influenzal attack, and after the temperature had been normal for a week he developed thirst and polyuria. On admission to hospital a month later the urine gave a positive ferric chloride reaction; the sugar disappeared after five days' treatment. The tolerance was tested 18 months later, when 500 g. of bread could be taken without glycosuria. After 50 g. of glucose glycosuria appeared and lasted for three hours.

LIGHT FILTERS FOR MICROSCOPIC WORK.

While for the ordinary purposes of laboratory technique the limits of microscopic vision have probably been reached with modern instruments, the results obtainable may be improved in many respects by a more careful manipulation of the means at our disposal. Kodak, Limited, have placed on the market a set of light filters for use with the microscope which should be of considerable value. These filters, known as the Wratten Visual "M" Filters, are distinct from the standard square sets used for photomicrography, being circular in shape with a diameter of 35 mm., and designed to fit the ring usually supplied with the ordinary substage microscopic fittings. They are sold in sets of nine and include a variety of tints, dark blue when the highest resolving power is required, green for contrast with pink- and red-stained specimens, red for contrast with blue- or green-stained specimens, and so forth. Two of the most useful of them are the neutral tint filter for modulating the intensity of illumination, and the "Tungsten to daylight" filter, which converts the light from an artificial illuminant to equivalent daylight. The latter should be particularly called for where daylight is not available, or where a constant form of illumination is required.

THE IMPERIAL WAR MUSEUM.

It is doubtful whether a collection of exhibits like those now on view in the Imperial War Museum, opened by H.M. the King at the Crystal Palace on Wednesday, has ever deserved such absorbing attention. The war trophies from sea, land, and air are one and all of a most interesting description, and they are there in profusion. Apart from projectiles, weapons, guns, and other war materials, there are two sections of particular appeal to the medical profession—the naval and army medical exhibits. These sections not only illustrate the splendid service rendered by our great medical administrations, but are instructive also in regard to the methods of the enemy in this direction, and the ultimate straits to which Germany was reduced as the end approached. Lace curtains, for example, were used for bandaging, and spring wire cloth was made to replace rubber, and so forth. Again, examples are presented of all the appliances employed against poison gas attacks, and in the steps taken to supply the men with oxygen and various medicaments in the submarine. Much of the medical history of the war is here in graphic form, and the pictures are a very striking and attractive feature of the exhibition. We understand that the War Museum is to be a permanent one, so that the opportunity of studying the models and exhibits is to be open for all time. But we recommend an early visit, while the memory of events is fresh.

SARCOMA OF THE BLADDER.

At a recent meeting of the Chicago Urological Society Dr. Charles Morgan McKenna[1] reported a case of sarcoma of the bladder in an unmarried woman, age 42, who had suffered from periodical hæmaturia from 4½ to 6 months. On cystoscopic examination a papillomatous growth was seen which involved the orifice of the left ureter. Fulguration was performed five times at intervals of five days, and subsequently a suprapubic operation was carried out and the tumour removed. The ureter was divided about 1¼ in. above its orifice and a transplantation made. Six months after the operation, when the case was reported, no recurrence had taken place. Histological examination of the tumour, which was about the size of a walnut and of very hard consistence, showed that it was a large spindle-celled sarcoma. According to Legueu sarcoma of the bladder is a very rare occurrence, only 55 cases having been recorded. It is more frequent in women than in men, and occurs mostly in early childhood and middle age. The tumour grows in the mucous membrane, is sessile, and rarely becomes pedunculated. It is usually situated at the base of the bladder in the neighbourhood of the ureter. Metastases are found in the bones, prostate, and iliac vessels, and secondary nuclei occur in the lungs, liver, and spleen. In the subsequent discussion Dr. Louis E. Schmidt, who reported three cases in patients aged from 19 to 25, confirmed the rarity of sarcoma and pointed out that the prognosis was much better than that of carcinoma of the bladder.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

The Case of Pandit Devi Dayal Sasun.

AT a meeting held on Wednesday, June 2nd, the Council proceeded to the consideration of this case. The charge was as follows :—

> That being a registered medical practitioner you were, at the General Session holden at the Central Criminal Court on April 13th, 1920, convicted of the following felony—namely, of unlawfully killing Elsie Maud Wright—and sentenced to ten years' penal servitude.

Sir ARCHIBALD BODKIN read the evidence of indictment, and Mr. HARPER, solicitor to the Council, detailed the facts, which showed that 116 documents were found from the same number of women on whom it had now been proved he had performed an illegal operation. There was no defence, and no questions were asked by members of the Council.

After deliberating *in camera* the PRESIDENT announced as follows: "Pandit Devi Dayal Sasun having been proved to have been convicted of the felony alleged against him in the notice of inquiry, the Registrar has been directed to erase his name from the Medical Register."

The Case of Alexander John Wood, M.B., C.M. Edin.

This practitioner had been summoned to appear before the Council on the following charge :—

> That being a registered medical practitioner you abused your position by committing adultery and eloping with Emma Jane Harman, a married woman, you having been the medical attendant of the family, of which adultery you were found guilty by the decree of the Probate, Divorce, and Admiralty Division (Divorce) of the High Court of Justice, dated Oct. 18th, 1918, and made absolute on May 5th, 1919, in the case of Harman *v.* Harman and Wood, in which you were the co-respondent. And that, in relation thereto, you have been found guilty of infamous conduct in a professional respect.

Mr. HARPER stated that the accused practitioner, formerly in practice at Poole, Dorsetshire, was now residing in Saskatchewan; a communication from him, addressed from Moosejaw, stated that he had no defence to make to the charge, "as the decision of the Divorce Court left me none," at the same time asking that, should his name be erased from the Register, it would be done without unduly dragging his name in the dirt again. Mr. Harper detailed the facts in the case, which the judge described as a very bad one. The adultery took place in 1912, and the petitioner stated that he could not apply for the decree until 1918, as he could not save the necessary money before the latter date—facilities for obtaining divorce decrees by the poor were not operative until 1915. Harman's wages were 30*s.* a week. The acquaintance of the parties began after the birth of Mrs. Harman's child, at which event he was in attendance.

After considering the matter *in camera*, the PRESIDENT notified the Council's decision as follows: "I have to announce that the Council have adjudged Alexander John Wood to have been guilty of infamous conduct in a professional respect, and have directed the Registrar to erase from the Medical Register the name of Alexander John Wood."

The Case of Frederick Arthur Pring.

The summons in this case bore the following charge :—

> That being a registered medical practitioner you abused your position by committing adultery with Dorothea Morris, a married woman, with whom you stood in professional relationship, of which adultery you were found guilty by the decree of the Probate, Divorce, and Admiralty Division (Divorce) of the High Court of Justice, dated Nov. 5th, 1919, and made absolute on May 17th, 1920, in the case of Morris *v.* Morris and Pring, in which you were the co-respondent. And that, in relation thereto, you have been guilty of infamous conduct in a professional respect.

Mr. Hempson (solicitor) appeared for the accused practitioner, who did not attend.

Mr. HARPER, in submitting the facts of the case, first alluded to the question of the relationship of the accused to the lady in the case, as Dr. Pring had alleged that he did not stand in a professional relationship with her. This point did not come before the Divorce Court, whose concern was as to the proof or otherwise of the alleged adultery, and it held the charge to have been proved. But with the General Medical Council the crucial point in such cases had always been as to whether the accused practitioner stood in the position of medical attendant to the lady or the members of her family. If this relationship were established here Dr. Pring must be held to be guilty of the charge of infamous conduct. A judge had declared "every bedroom in the village is open to the doctor." Mr. Morris brought divorce proceedings against his wife, with Dr. Pring and another man as co-respondents. As the case against the other man was not tried it would be unfair to use his name in the case. The case against Dr. Pring was tried and was answered formally by Mrs. Morris and by Dr. Pring, both denying the charge; and Mrs. Morris countercharged Mr. Morris with committing an unnatural offence upon her, which, if proved, would have disentitled Mr. Morris to a decree. It was held that no unnatural offence was committed. The onus now lay upon the accused practitioner to support his statement that he was not acting as medical attendant to Mrs. Morris, but he was not present to do so. On receiving the notice from the Council the accused practitioner wrote that he did not commit adultery, despite the decree, and that he did not stand in a professional relationship with Mrs. Morris. Mr. Harper said the statement was amazing to him, as he did not think there could be a clearer case of professional relationship. He proceeded to read portions of the 400 pages of evidence given at the trial, and from documents, to support the following points. Dr. Pring was acquainted with Mrs. Morris before her marriage (as Miss Tate), and after her marriage he frequently lived at the same hotel as Mr. and Mrs. Morris, at different places, and during the husband's absences was a frequent visitor. She at this time never went out alone with her husband, but frequently did so with Dr. Pring; later she refused to allow her husband to share her room. Subsequently she removed to Dr. Pring's house, where he agreed to treat her, and forwarded reports to her husband. Mr. Harper read a number of accounts of charges for professional attendance.

At this stage Mr. HEMPSON said now the correspondence had been read he could not ask the Council to go into the question of professional relationship as if it were contested.

Mr. HARPER read the lady's confession of adultery with Dr. Pring, extending over a considerable period.

Mr. HEMPSON briefly addressed the Council in his client's behalf, in which he contended that the evidence of misconduct was purely inferential, although he fully agreed that affection between the two had been proved. Mere contiguity of rooms at a hôtel proved nothing. He called a witness as to character, Dr. J. C. Bentley, who was second in command of the Reserve Battalion to which Dr. Pring was attached.

Dr. J. C. BENTLEY stated that Dr. Pring and he were very friendly, and he never saw any behaviour between Dr. Pring and Mrs. Morris (whom Dr. Pring constantly referred to as his ward) other than what was proper for such a relationship during his many visits; and certainly all the senior officers knew the lady was married.

The Council then deliberated on the case *in camera*, and when strangers had been readmitted the PRESIDENT said: "I have to announce that the Council have judged Frederick Arthur Pring to have been guilty of infamous conduct in a professional respect, and have directed the Medical Registrar to erase from the Register the name of Frederick Arthur Pring."

Reports of Committees: Professional Examinations.

Dr. NORMAN WALKER moved the adoption of this report, which was concerned with the inspection of the examinations of the Apothecaries' Hall, Dublin, in 1919, by Dr. Finny, who was deputed to the work by the Council. It was a favourable report, Dr. Finny expressing the view that, if persevered in, the high tone of the examiners would raise the examination to the level of that of the Royal Colleges. He objected, however, to the piecemeal methods by which some candidates qualified. The report was adopted.

Dr. WALKER then proposed that the further report of the Examination Committee be adopted. This dealt with the examination tables for 1919 and on instruction in ophthalmology. There was a tendency for the licensing bodies to give less information than formerly as to operative surgery, ophthalmology, and mental diseases. The Council agreed to the recommendation :—

> "That the licensing bodies which have not hitherto supplied in the return information as to whether they do or do not examine in operative surgery, ophthalmology, and mental diseases be asked to do so in future."

Dr. WALKER said that reports were still lacking from some licensing bodies to show how far their regulations were in accordance with the recent recommendation of the Council concerning the teaching of ophthalmology. It was to the effect that every student should be required to attend a course of practical instruction in this subject of not less than ten weeks, and that no student should be allowed to sit in the Final Examination unless he presented a certificate stating that he had regularly attended such a course and that his work in the course had reached a satisfactory standard. The Committee appended the replies on this subject which had been received from 18 licensing and teaching bodies

The Council agreed to the usual recommendation that the Dublin Apothecaries' Hall be requested to furnish tables of exemptions from examinations, and the results of examinations as heretofore The Report of the Examination Committee as a whole was then adopted.

Dr. WALKER further stated that reports on the inspection of final examinations had been received from inspectors in reference to the examinations of the Conjoint Board in England on medicine, surgery, and midwifery, and of the Apothecaries' Society of London on medicine and surgery. It was agreed, however, that it would be wise to defer detailed comment upon them until the receipt of reports from other bodies, thus enabling a review to be made of the whole of the examinations.

Following this the Council deliberated on a number of matters *in camera*, and, on resuming the public hearing, considered the report of the Education Committee in regard to the duties devolving upon practitioners in their relation to the State and medical ethics, of which Committee Dr. Mackay is chairman. Replies on the matter had been received from 26 licensing and teaching bodies, and the general effect of these the Committee considers to be that the Council's recommendations were being given effect to. Some of the bodies promised more attention to the subject in the future.

Report of Public Health Committee.

At a meeting held on Thursday, June 3rd,

Sir JOHN MOORE, chairman of the Committee, submitted this report. He pointed out that among all the medical authorities granting the D.P.H., exemptions were granted in only three. 136 candidates passed the first examination, and 49 were rejected; the final was passed by 146, and the rejections numbered 48. The figures showed an increasing recognition by the public services of this higher qualification, especially in regard to preventive medicine. He said the Committee had considered two further communications from the Director General of the Medical Department of the Admiralty on the question of facilities for medical officers of the Navy. The first of these stated that the question of extended study-leave to medical officers in the Royal Navy who wished to take the D.P.H. was under consideration; and the second accompanied a copy of the syllabus for the two months' instruction at the Royal Naval Medical College, Greenwich.

The following recommendations at the end of the Committee's report were then discussed and eventually carried in due form, the PRESIDENT pointing out that there was no intention to cut down the total period of study in the least; it was merely putting the navy on the same footing as the army in this respect, and allowing the course to be taken in two parts at two places.

1 That the Council approve the instructions given to naval medical officers at the Royal Naval Medical School, Greenwich, before promotion, in the subjects of hygiene and bacteriology (systematic and practical laboratory courses) being accepted as equivalent to two months of the nine months curriculum required for the Diploma in Public Health.

2 That the course in hygiene at the Royal Medical School, Greenwich, required for promotion in the Royal Navy Medical Service, be considered equivalent to the instruction given by a teacher or teachers in the department of public health of a recognised medical school under Rule 3 (*f*), Note I 1.

3 That the Council approve the proposal of the Committee to defer its detailed remarks upon the reports of the inspector in public health until the inspection has been completed, so that a general review of the examinations as a whole may be made

Students' Registration Committee.

Sir NORMAN MOORE, the chairman of the Committee, submitted this report It gives a list of applications for exceptional registration as students, or for the antedating of the commencement of professional study. With the exception of the case of Mr Wills, who applied to have the course of study which he took out at Meharry Medical College, Tennessee—for the M.D.—recognised, the report was approved. Meharry College was not thought to be of a sufficiently high standard. The Council's approval embraces the recognition of the following institutions the Perse High School for Girls, Cambridge; Kingswood School, Bath; and Wellingborough School.

Report by Education Committee on Practical Midwifery.

Dr. MACKAY presented this report, and moved its reception.

Sir FRANCIS CHAMPNEYS, in seconding, passed the report under review, and added his views on the present-day position of the subject.

He thought it was being realised that midwifery was more directly associated with preventive medicine than with any other branch of medicine or surgery It had been a long time getting into its due place—it was not there even yet. Medicine and surgery had always taken the lion's share in regard to beds and the amount of instruction insisted upon in order to qualify to practise. The modern development of midwifery had been largely along the lines of chemistry and bacteriology, especially in regard to the still obscure chapter concerning the toxæmias of pregnancy. The obstetrician stood at the gate of life, whereas medicine and surgery were concerned with combating deviations from the normal. The case of the pregnant woman was a matter of very great importance, especially in dealing with and preventing the effect of venereal disease; it could be combated before delivery. Gynæcology could be regarded, in practice, as the clearing up of the débris of bad midwifery, and if midwifery were good much of the gynæcology would be unnecessary.

Sir Francis Champneys then discussed the heads of the inquiry addressed to the recognised teaching institutions on the carrying out of the General Medical Council's recommendations The requirements from candidates for a licence to practise were :—

1 Every student before commencing the study of practical midwifery should have held the offices of clinical medical clerk and surgical dresser, and should have attended a course of lectures on surgery and midwifery.

2 Every student should be required to present a certificate bearing evidence that he has conducted 20 cases of labour under official medical supervision, subject to the following conditions either (*a*) that he has previously given regular attendance for a period of three months upon the indoor practice of a lying in hospital or the lying in wards of a general hospital, and has received practical instruction therein; or (*b*) that he has previously given regular daily attendance for a period of one month upon the indoor practice of a lying-in hospital, or the lying in wards of a general hospital or Poor law infirmary having a resident medical officer, recognised by one of the licensing bodies, and that he has conducted cases of labour therein and has been certified by his instructor as competent to conduct outdoor cases under official medical supervision

3 The certificate that the student has conducted the above-mentioned 20 cases of labour should be given by a member of the staff of a lying in hospital, or the maternity charity of a general hospital recognised by one of the licensing bodies, or of a dispensary having an obstetric staff, or a Poor law infirmary having a resident medical officer similarly recognised

He said the recommendations of the Council had been received with general goodwill Several of the teaching bodies were unable to provide 20 cases for each student owing to insufficiency of material The first necessity was a large increase in lying in beds, without which adequate instruction at the bedside was impossible A reduction in the number of required cases per student would lower the standard A large number of the women trained for the examinations of the Central Midwives Board never intended to practise as midwives, hence the cases allotted to such women during their training were, in regard to the primary requirements of the State, wasted In 12 years the cases of which this could be said numbered 356,420 The lying in beds now available at the London medical schools would not suffice for the complete education of all their students Meantime he emphasised the necessity of intensive culture with respect to cases in the out-door maternity departments, students should be diligently taught upon such cases. The passing of the Midwives Act, 1902, was followed by a marked drop in puerperal mortality, and it had never since risen to its former level A certain number of students would receive in patient training—to be followed by out patient training—if a redistribution of beds were made in the general hospitals

The Education Committee believed that the present difficulties might be greatly alleviated First, in regard to the deficiency of lying-in beds, by the utilisation of beds in Poor law institutions under skilled instruction, and secondly, in reference to the deficiency of lying-in cases by the limitation of candidates for the certificates of the Central Midwives Board to pupils who have given undertakings to engage in practice as midwives for not less than three years after qualifying. Thirdly, the difficulty in regard to instruction could be largely met by the improvement in the quality of the teaching at the bedside in lying-in wards and in out-patient maternity departments. The Committee considers that the teaching of midwifery should be as thoroughly practical as that of surgery.

A general discussion on the subject ensued.

Dr. Dean (Manchester) assured the Council that the regulations were fully carried out at Manchester University. In fact, many students went there for this training because they could not get the accommodation and facilities in their own school.

Mr. G. Turner thought this one of the most important matters which could come before the Council at the present time, because cases of labour among the industrial classes were more and more passing into the hands of the qualified midwife—a beneficial change from the old septic "handy woman"—with the result that the function of the practitioner was becoming more than ever that of consultant in the midwife's cases in which difficulties presented themselves. This the practitioner in many cases did not favour.

Sir Gilbert Barling said he hoped they would not wait for the medical millennium before establishing the proper teaching of midwifery. The Poor-law authorities were anxious to promote what the Council desired. He hoped the teaching of midwifery would not be divorced from that on the subject of diseases of women. It was not desirable to train the medical student and the midwife in one institution; if any such attempt were made, one or the other would suffer injustice. Provision in this matter should be made at once, otherwise the large number of people now entering the profession could not have the necessary training.

Dr. Matthew Hay said medical men were not too ready to certify puerperal fever as a cause of death; but in Aberdeen for some years he had asked the registrar to inform him of the death of any woman occurring within four weeks of child-birth, whatever the cause was declared to be, and cases were found to have been due to puerperal fever which were not so certified. The Poor-law was about to die, and in Scotland women showed a strong disinclination to go to their institutions; they preferred to go to other places, even to be confined in unsatisfactory lodgings. He would like to be able to choose for maternity work women who had had a previous hospital training.

Sir George Newman agreed as to the need to take practical steps at once. Many proposals came before the Ministry of Health for the establishment of maternity homes, but the building of such institutions was likely to be postponed for some time to come because of the need of ordinary dwelling-houses. Half the general beds in this country were in the possession of the Poor-law authorities, about 90,000, and 30,000 of these might be available for hospital purposes. Amid great difference of opinion on nearly all subjects, everyone seemed to agree that there should be adequate provision for every child at the moment of birth. He did not hope for a proper utilisation of Poor-law accommodation until the supposed stigma attaching to the name had been conquered.

Sir John Moore said that in the Royal College of Physicians in Ireland this was a very burning question. He urged the discontinuance of the use of the term "Poor-law," and asked that Ireland be excluded from the recommendation. This was conceded.

The President said that a change in this regard had come over the local authorities, for, in contrast to the condition years ago, the Local Government Board and the Ministry of Health were now anxious that the Poor-law and maternity institutions should be fully utilised for the purposes of clinical teaching.

The report and the following recommendations were agreed to:—

That a communication be addressed to the Ministry of Health and the Board of Health of Scotland begging that steps may be taken for the utilisation of existing Poor-law institutions for clinical instruction, and that such instruction shall be placed in the hands of experts; further, calling attention to the desirability of limiting the acceptance of candidates for the C.M.B. certificates to those who give an undertaking to engage in the practice of midwifery for not less than three years after their qualification.

It also recommends that the attention of recognised teaching institutions be again called to the recommendations of the Council issued to them in 1906, in the hope that, when the present difficulties in training are alleviated, they may be able to carry out these recommendations in their entirety, and that the present conditions of training, which in many cases cannot be approved, may be rendered sufficient and such as the Council will be able to regard as satisfactory.

The Dental Education and Examination Committee.

The discussion of these reports occupied the rest of the day's sitting, and a report of the adjourned proceedings will follow next week.

THE ARMY MEDICAL SERVICE:

A GREAT APPRECIATION.

A dinner was given in appreciation of the services of the Royal Army Medical Department and the eminent civilians attached to it during the war on Tuesday last, at the Connaught Rooms, under the chairmanship of Lord Midleton. The hosts, many of whom it will be seen have held, or are holding, the highest positions at the War Office, were the following:—

Viscount Burnham, the *Earl of Derby, the Earl of Donoughmore, Viscount St. Davids, Lord Desborough, Sir John Ellerman, Earl Fitzwilliam, Sir Alan Hutchings, Sir Heath Harrison, Bt., Mr. Vesey G. M. Holt, Lord Harris, Lord Inchcape, Viscount Knutsford, the Marquis of Lansdowne, Sir Walter Lawrence, Bt., Lord Lee of Fareham, the *Earl of Midleton, Sir William B. Peat, Sir Ivor Philipps, Lord Queenborough, Sir Samuel Scott, Bt., the Marquis of Salisbury, Lord Somerleyton, the *Right Hon. J. E. B. Seely, the Earl of Scarbrough, the Hon. Sir Arthur Stanley, the *Right Hon. H. J. Tennant, *Lord Edmund Talbot, *Sir Edward Ward, Bt., and Lord Wavertree.

Those with an asterisk formed the dinner committee.

Sir Edward Ward took on the task of secretaryship.

After the King's health had been drunk, Lord Midleton proposed the only toast of the evening—namely, "The Royal Army Medical Department and the Eminent Civilians Attached to it," coupling the toast with the names of Lieutenant-General Sir Alfred Keogh, Director-General during the first four years of the war; Lieutenant-General Sir John Goodwin, his successor and the present Director-General; and Sir George Makins, President of the Royal College of Surgeons of England and late consulting surgeon to the armies in France.

Lord Midleton said that he believed this was the only case since the armistice that a particular branch of the army had been the object of a public ovation, and that it was remarkable when contrasted with the past attitude of the nation to all but the combatant branches of the army in other wars. In every war up to the present the medical service had been hurried into the field, although starved in numbers for peace service, insufficiently paid, without leisure or opportunity for scientific training, separated by a water-tight partition from the great civil profession which could be its only effective reserve, with scant opportunity for practising modern surgery, and confined to a medical curriculum the records of which were mainly a study in erotic literature. There were men in that room who could remember the days when in a large cantonment the only site assigned for a hospital, where capital operations were to be performed, was a vacant spot between a dust-heap and a slaughter-house, and when the last man to hear of any intended move of the army was the senior medical officer. To a department so restricted peace was a necessity. But if a review were to be now held of the departments of the army, and the award of excellence given solely for progress since 1900, he would make bold to say that the Commander-in-Chief in ordering the parade would not be unlikely to place the Army Medical Department on the right of the line. Nowadays the men who held commands in peace were so chosen as to hold the same commands in war, the equipment designed for peace was the same as the equipment for war, the gap between civilian and professional soldiers was so bridged over that the professional service could be developed into a national force. These principles were so applied by the Army Medical Department in the years before the war that it conciliated to itself the entire support of the great civilian profession, the most eminent members of which were there that night. The equipment was so overhauled that no change was necessary in it in any of the campaigns since 1914 A sanitary branch was organised in 1908, and while typhus was kept wholly at bay enteric fever received a knock down blow, as the figures for the South African War showed, compared with British figures for the recent war Inoculation had won as many battles for us as any one of the distinguished commanders present that night, while the man who discovered the 'Leishman bacillus" deserved as much of his country as the man who invented the Lewis gun The Royal Army Medical Corps, which consisted of 800 officers and 9000 other ranks in July, 1914, was developed to 16 000 officers and 132 000 other ranks in 1919, and exceeded in numbers the original Expeditionary Force Beyond *these thousands of busy practitioners attended hospitals for hours daily, refusing all remuneration*, 18,000 V A D s gave their services in these hospitals for years together, and 2000 masseuses provided by the public spirit of Lord Queenborough, served under the direction of Miss French Can you, asked Lord Midleton, have a higher tribute to any corps than that the nation thus mobilised itself in its support? With these reinforcements the Army Medical Corps, who having 2000 patients in hospital in 1914 attended 577 000 in 1919, and as early as July, 1916 received 48 000 patients in hospital in a single week We owe it to the successive heads of the Army Medical Department at home and abroad that these gigantic developments *did not lead to hopeless confusion* Our *army* was the *only one of all the combatants* which had *to conduct six different expeditions* at the same time It would be strange if with the desperate gamble of the Dardanelles the sudden stroke in Salonika, the mirage of Mesopotamia, all coincident with overwhelming claims in France, we had entirely avoided military miscalculations and consequent medical perplexities But through these difficulties the Army Medical Department, with its immense civilian retinue, marched breast high to ultimate success Lord Midleton concluded his speech as follows ' There sits upon my right to night as our chief guest the man who typifies the administrative genius, the executive efficiency and the scientific skill which enables us to thank *our guests not merely for great service to the* Empire but *for the position which they have won for* Great Britain in the scientific world It is due to him, to his able successor Sir John Goodwin and to the magnificent civilian assistance, typified by Sir George Makins, that the magnificent tribute can be paid to the Army Medical Department that the Department stands well with the army '"

Mr WINSTON CHURCHILL asked when every form of national effort producing the devices of destruction had received its tribute of popular applause why should those, who in equal danger and in equal hardship had been saving life not receive their meed? He pointed out that, when our island *nation*, with its *Empire gathered about it* plunged into war, so vast *an expansion of everything, offensive*, defensive and protective, had to follow, that those were found right in their forecasts who dared to think bigger than anyone else As a measure of the expansion in bulk of the work of the medical services he said, when the war began there were 7000 beds available, and when it ended there were 700 000 beds occupied In a passage of great eloquence he urged his audience to imagine what it must have meant to thousands of homes and hundreds of thousands of men in periods of the greatest human weakness and misfortune to know that the great mass of suffering misery, and *shattered figures which represented war could* cast itself upon the mercy of the Royal Army Medical Corps, never to find that mercy lacking, and he illustrated his meaning with a remarkable and personal picture of a large casualty station a few hours after a battle has begun Mr Churchill closed his speech by an acknowledgment of the immense services rendered by eminent civilians and gracefully confessed himself to have been in former days Lord Midleton's critic "youthful ignorant and hard" so that he rejoiced in the opportunity, which supporting the toast gave him *of saying that Lord Midleton s work in the* organisation of the army, following the Boer war had been in its most important respects signally vindicated

Field Marshal Earl HAIG described the work of the medical units attached to his own command during the fighting on the Aisne and dwelt on the extraordinary difficulty of the circumstances in which that work was carried on He went on to say that the Royal Army Medical Corps throughout the war had been absolutely splendid unselfish, and devoted while as the army grew the medical service had grown *in efficiency as well as size* He testified to the happy relations which existed between the Regular R A M C, the Temporary, and the Territorial officers and the rest of the army, acknowledging in conclusion, his personal and lasting debt as Commander in Chief to those in authority over the Army Medical Department during the war, making special allusion to Sir Arthur Sloggett Director General in France from 1914 to 1918

Sir ALFRED KEOGH said that on such an occasion it was completely impossible for him either in the time at his disposal or in any unlimited time to express all that should be said That night gave the Army Medical Department a triumph after more than 60 years of endeavour on their part to become efficient The beginning of that endeavour he traced to the influence of the great Sidney Herbert, who after the Crimean War took the lead in the movement for army medical reform, and was the mainspring of the first Royal Commission on the Sanitary Condition of the Army The movement thus started said Sir Alfred Keogh, did not progress with any strength, and nothing much was done that was practical until God sent the cause of medical reform two men—Midleton and Haldane Lord Midleton gave the officers of the Royal Army Medical Corps *the opportunity for post graduate study which made their scientific position sure* and he *founded* the school in London Lord Haldane brought the Regular medical officer of the army into close touch with the civilian branch of his profession, a thing which the R A M C had always craved for Alluding to the conduct of the R A M C in the war, now receiving a testimony which words failed him to describe, Sir Alfred Keogh pointed out that none of their improvements in sanitary science or education would have been of the least use had it not been for the intelligent sympathy of commanders in the field, commanders in the air, and battalion and company commanders who cared for the health of their men He pointed out that in the Mediterranean area Field Marshal Lord Methuen as *Governor of Malta*, had filled the *position of a great coordinator of all medical effort*

The toast was replied to also by Sir JOHN GOODWIN and Sir GEORGE MAKINS The Director General declared that the work of his department could not have been carried on with any success had it not been for the hearty cooperation of the War Office and the devoted industry of his staff, while he took the opportunity of reminding the audience how much our medical services at the beginning of the struggle owed to the voluntary aid of American surgeons Sir George Makins, replying for the civilians attached to the corps, briefly but sincerely acknowledged the unique compliment paid to medicine on the occasion, and alluded to the advantages which had accrued to medicine through the wide interchange of knowledge in unparalleled conditions

The company at dinner included—

Field Marshals Earl Haig and Lord Methuen

Generals Sir Ian Hamilton Lord Horne Sir Archibald Murray, Lord Rawlinson

Lieutenant Generals Sir William Babtie V C Sir T E Clarke, Sir John Goodwin Sir L Gubbins, Sir Alfred Keogh, Sir G M Macdonough Sir Arthur Sloggett

THE NATIONAL COUNCIL FOR COMBATING VENEREAL DISEASES.

THE fifth annual meeting of the National Council for Combating Venereal Diseases was held in the Barnes Hall of the Royal Society of Medicine on June 7th, when there was a very large attendance.

Lord SYDENHAM, who occupied the chair, said that owing to advancing years he was retiring from the Council as President, but expressed his deep interest in the movement, which had never been so vigorous or so progressive as at the present time. Beginning in London on a small scale, the organisation had now branches all over the country.

Few people realised, he said, the difficulties with which the Council had to deal, involving as they did both problems in physiology and psychology, as well as the opposition of ignorance and prejudice. The work needed the coöperation of medical men and laymen and women, while the moral side required the aid and support of religious bodies, who, however, in many cases did not seem to realise the great danger to individuals and to the race which resulted from venereal diseases. If the teachings of the Council were universally adopted much would be done to stamp the disease out of the country. Already a vast amount of propaganda work had been done, and probably two and a half million people had been reached. A large sum of money had been spent in clinics in towns, but the rural areas had not been reached, and here the help of the general practitioner was required. The results of clinics could not be considered altogether satisfactory, for of the 175,000 people who had been treated about half had left before treatment was completed. Means would have to be found sooner or later to prevent this waste of public money. All the Dominions had set up organisations affiliated with the National Council, and the Treasury had helped in sending two commissions to eastern and western groups of colonies, aid having also been received from the Colonial Office. The Empire was thus being subjected to valuable spade work, and information was being exchanged with America. The setting up of a health section with a permanent bureau in connexion with the League of Nations would be good for society at large. Red Cross were instituting similar movements, and the cordial relations between the Ministry of Health and the Council were making for progress in many directions. But continued and united efforts were necessary to free the country from a scourge which affected the whole life of the nation and menaced the race at a time when the most vigorous citizens in mind and body were needed.

Lord ASTOR said that the Ministry of Health recognised the work of the Council to be on sound lines. In attacking disease of all kinds voluntary effort could do much which a Government could not do, and it was of vital importance that the country should have a clean bill of health. Lord Astor continued:—

The war had left a legacy of venereal disease coupled with a reduction in the birth-rate. Statistics were not available, but the attendances at institutions for the treatment of venereal diseases had increased, and he was glad that the efforts of the Ministry of Health had encouraged people to come and be treated. Deaths from syphilis, general paralysis of the insane, and locomotor ataxy were not increasing. This, however, did not mean that the extent of venereal disease was not serious. Compulsory treatment was being advocated, but it was first necessary to provide enough facilities for diagnosis and treatment for those affected. Compulsion would inevitably lead to concealment and failure to apply for treatment. During the war venereal disease was reduced more by women police and drink control than by the 40D and 13a regulations. State interference and compulsion on the continent had not produced populations which were cleaner or healthier in mind and body than our people, while in this country the C.D. Acts had never been a success. In regard to "packets," their value had not been proved, and the risk to health and the welfare of the community would be serious. Their use in the army, where the men could be regularly examined, and where they could be punished or controlled, was a different matter. It was necessary to stimulate medical education and bring the general practitioner more into touch with modern medical science, and the Ministry of Health proposed to work through the medical schools and the V.D. clinics, of which there were now 172; but more and better ones were needed. Rural areas afforded special difficulties, for the same privacy could not be obtained as in town. Greater facilities were needed for diagnosis and treatment, with special reference to the needs of seamen and of pregnant women. The temptations of our seafaring population must be kept in mind. More hostels for girls were also wanted, and propaganda must be increased both for adults and adolescents. Finally, he hoped that the League of Nations, through its health section, would help to solve the V.D. problems as well as many others.

Lord GORRELL, who succeeds Lord Sydenham as President of the National Council, proposed a vote of thanks to Lord Astor for his address and support, which was seconded by Sir MALCOLM MORRIS, who said that in rural communities the general clinic was needed, where *all* people could go for *all* diseases, when secrecy would be kept; therefore, with regard to venereal diseases.

The proceedings terminated with a vote of thanks to the chairman.

SOCIETY FOR THE PREVENTION OF VENEREAL DISEASE.

THE first annual meeting of this society was held on June 3rd in the Barnes Hall of the Royal Society of Medicine, Lord WILLOUGHBY DE BROKE presiding.

The CHAIRMAN after recalling the origin of the society, as due to the common-sense view that to avoid contagion contact must be avoided, pointed out to his audience that, inasmuch as a little knowledge, especially uninstructed, unscientific knowledge, is dangerous in the highest degree, it was important that the truth should be made available for the public under the control and with the supervision of qualified medical authorities, such as the Ministry of Health, medical officers of health all over the country, or any other public body qualified to say what is and what is not a disinfection against venereal disease. It was for that policy that he invited the cordial coöperation of those present, and the following resolution was put to the meeting:—

> That inasmuch as the Ministry of Health has failed, and public bodies, including the London County Council, have declined, to provide the means of delayed disinfection against venereal disease at ablution centres, this meeting calls upon the Ministry of Health and upon local authorities to instruct all qualified chemists to sell such means of immediate self-disinfection against venereal disease as may be approved from time to time by the Ministry of Health or medical officer of health.

Lord Willoughby de Broke repelled the accusation brought against the society that the establishment of disinfectant centres, with information how to use them, would be a deliberate invitation to promiscuous intercourse, and denied that members of the society could be accused either of incitement to immorality, or of default from the high moral aim of attempting the promotion of public health.

Dr. C. W. SALEEBY, Sir JAMES CRICHTON-BROWNE, Sir FREDERICK MOTT, and Sir W. ARBUTHNOT LANE supported the resolution. Sir FREDERICK MOTT confirmed the two first speakers in their statements that the disabilities produced by syphilis were colossal, and said that the support of the Government to the propaganda of the society was necessary from the health and economic point of view. Sir W. ARBUTHNOT LANE, having regard to the membership of the society, said that it ought to be called the "Suicide Club," as it consisted of a body of men who made their living out of the ravages of syphilis, and who were determined to restrain or abort those ravages.

The CHAIRMAN put the resolution to the meeting and declared it carried unanimously.

Mr. H. WANSEY BAYLY, the honorary secretary, said that the progress made during the seven months of the society's existence had been most encouraging.

Two public meetings, he said, were held in London, the first at the Central Hall, Westminster, and the second at the Mansion House, under the presidency of the Lord Mayor. Medical officers of health throughout Great Britain had been circularised on three occasions, with the gratifying result that 12 councils had endorsed the policy of the society and had recommended that the opportunity of acquiring knowledge in regard to efficient and immediate self-disinfection should be given in their districts. 20,000 pamphlets had been distributed, and 15,000 leaflets of directions on demand from various centres and individuals. Provincial and colonial branches were being established, and a strong Parliamentary Committee had been formed to further the aims of the society. On the whole, the press was sympathetic, and the lectures given under the auspices of the society on the prevention of venereal disease were much appreciated. Mr. Wansey Bayly said that this society stood for the principle that it is immoral to withhold a scientific truth from the people, the knowledge of which will diminish disease, pain, and sorrow. He therefore made an appeal to each member not to consider his obligations as ceasing with the payment of his annual subscription, but to act as a centre for the dissemination of knowledge, the increase of membership, and the collection of funds.

Sir JAMES CRICHTON-BROWNE and the Rev. HUGH CHAPMAN having spoken to the report, Dr. J. H. SEQUEIRA moved that it be adopted. This was seconded by Dr. R. A. LYSTER, and the adoption of the report was carried unanimously, the CHAIRMAN taking the opportunity of testifying to the zeal and hard work of Mr. Wansey Bayly.

The meeting closed with the usual votes of thanks.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Difficulty of the Dublin Hospitals.

AT present nearly all the voluntary hospitals in Dublin are handicapped by heavy debts. While their expenses have nearly doubled their subscriptions have fallen off. Eleven of them, therefore, are uniting in a joint appeal to the public for the sum of £100,000 to pay off their debts. Sir Henry McLaughlin, who organised Red Cross appeals with great effect in Ireland, has taken on the duty of honorary organiser, and it is his intention to inaugurate and advertise the appeal by a fête to be held at Bale's Bridge in October. A public meeting was held in Dublin last week to elicit support for the hospitals, and the plans of the organisers were announced by the Lord Chancellor, and Sir Henry McLaughlin and others. It must be admitted that the attendance at the meeting was disappointing, and so far there is little evidence of public interest being aroused. But from the point of view of the hospitals the situation is critical. They cannot keep their doors open unless they get solid financial support. Even the liquidation of their debts will be at best a temporary relief. Their normal expenditure cannot again be brought within their normal means. Some new source of income must be tapped, and it is a question for those concerned in hospital management to decide whether to seek voluntary, municipal, or State aid.

It is interesting to note that the question of amalgamation of the Dublin hospitals, much discussed inside the profession last winter, is now being raised in lay circles. In a recent speech the Provost of Trinity College appealed to the hospital physicians and surgeons to give definite guidance to the public as to whether they were in favour of amalgamation or not. and there is no doubt an answer will have to be given. There may, indeed, be doubt as to whether amalgamation would cause any saving in money, but there can be no doubt that it would give greater efficiency.

Sir William Taylor's Knighthood.

The profession of Dublin has learned with much pleasure of the bestowal of the K.B.E. on Colonel William Taylor, formerly President of the Royal College of Surgeons in Ireland. He has been for many years one of the most prominent and active surgeons in Dublin. He was President of the College during two of the most strenuous years of the war. He has been consulting surgeon to the army in Ireland since early in the war, and he served abroad in the Dublin (83) General Hospital, the personnel of which he had organised at the invitation of the War Office. For his services in France he was mentioned in despatches and awarded the C.B.

The Housing Problem.

As a result of a recent inquiry held in Belfast, in an application from the city council for power to borrow £2,000,000 for the erection of houses, the Local Government Board has replied giving the corporation sanction to raise a loan of £500,000.

Health Exhibition.

The Health Exhibition organised by the Women's National Health Association and the Belfast Council of Social Welfare visited, during the week commencing May 24th, the west side of the city of Belfast, and was located at the Foresters' Hall, Divis-street, where Dr. R. J. Rowlette (Dublin) lectured on "Physical Degeneration," showing by statistical and other evidence the risk of deterioration in physique; Dr. Prudence Gaffikin on "Child Welfare," illustrating the value from the practical work of welfare centres; and Professor St. Cl. Symmers on "Milk," emphasising the importance of clean dairying and of pure milk. During the week beginning May 31st the exhibition moved to the east side of the city, where it was housed in the Mountpottinger Y.M.C.A. Lectures were delivered on three nights by Dr. W. Calwell on "Health in the Schools," who pointed out the deplorable state of the primary school premises in Belfast, and showed that, according to the opinion of the medical officer of health of Belfast, there were, out of a total of 286, only 17 first-class schools. Of the remainder, 99 were classified as "good," 89 as second-class, and 81 as third-class, and the medical officer declared that as regards the latter nothing could be done. Mr. W. J. Gilliland, F.R.I.B.A., gave an address on "Housing," in which he condemned the Irish Local Government Board plans of housing, spoke of existing streets of working men's houses as "interminable rows of unmitigated ugliness," and criticised severely the labour leaders for not allowing enough output. It was, he said, "not the workmen but the loud-mouthed demagogues who were to blame." Dr. H. L. McKisack lectured on "The Importance of a Healthy Mouth."

June 8th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Fixation of Cyanides by Tuberculin.

Two Lyons doctors, MM. Cordier and Morenas, have just discovered a new reaction of tuberculin, which may have an interesting bearing on the diagnosis of tuberculosis. They have proved that tuberculin fixes cyanides. When 3 drops of a 1 per cent. solution of iron perchloride, and 25 drops of a 1 in 100 solution of tuberculin, are added to a solution of 1 in 10,000 potassium ferrocyanide, the anticipated deep blue colour is not obtained. With 10 drops of tuberculin the colour becomes grey, and with 5, pale blue. No other human protein appears to possess this power. Applied to tuberculous individuals, this reaction would seem superior to the albumin reaction of the sputum. It would be very useful in the examination of cerebro-spinal fluid in suspected tuberculous meningitis.

Researches on the Nature of Cancer.

Interesting progress appears to have been made in the researches on the nature of cancer now being carried out in the laboratory of the Collège de France by M. Champy. Repeating the well-known experiment of Carrel, he has kept alive, and even in active mitosis, fragments of living human tissue in special media, confirming the fact that the anatomical element in cultivation reproduces indefinitely cells of the same type, kidney cells producing kidney cells, epithelial cells producing epithelial cells, and so forth. However, on prolonging the experiment he has found that after passing through a large number of cultures the new cells lose their specific characters and become young indifferent cells, such as those seen in cancer. Cancer would thus seem to be not a parasitic disease, but a definite disturbance of the normal mode of regeneration of cells, and this would explain the frequent appearance of cancer at the site of an old scar or of a chronic inflammatory process. M. Champy has been able to obtain cells of a malignant type after long cultivation of cells from a benign tumour. It would appear that in the normal state this proliferation of new cells is controlled by an inhibitory power which disappears with age or in susceptible subjects.

Antityphoid Vaccination of Children.

Professor Vincent, of the School of Military Studies at Val-de-Grâce, to whom is due the use of antityphoid vaccine prepared by sterilisation of typhoid bacilli by ether, organised during the war antityphoid vaccination of the whole army with a brilliant success, for, from the year 1918, the military typhoid mortality in France has been practically nil among 8 to 9 million mobilised men. Even at the present time cases of typhoid fever are rarely seen in the civil hospitals, and then almost always amongst the wives and children who have not undergone vaccination. The malady, however, has not yet disappeared from France, and it flourishes still in the South, particularly in Provence. M. Vincent concludes that in order to bring about the extinction of the scourge it is necessary to enforce antityphoid vaccination on the civil population, as has been done for vaccination against small-pox; it is necessary to vaccinate preferably in infancy, the infant bearing better the vaccination than the adult, with a very much slighter febrile reaction. The rule of re-vaccination at the end of three years should not be taken as absolute, as M. Vincent has been able to follow up the cases of soldiers vaccinated in Morocco in 1911 and who in 1920 still showed, at least half the number, an absolute immunity. When a person has been properly vaccinated, says M. Vincent, it is efficacious for a considerable time, and those who have been long ago vaccinated and have not been revaccinated within the recognised period, and who contract afresh typhoid fever, only present a mild type of the disease. All children ought to be vaccinated, at least in districts where cases of typhoid fever still occur.

Anaphylactic Vomiting in an Infant Treated by Injections of Milk.

An interesting observation has just been reported at the Société de Pédiatrie by M. Génévrier. A newly-born infant exhibited an absolute intolerance to milk, which he vomited immediately. A dozen attempts to feed with milk of various sorts (concentrated, butter-milk, whey, human milk, and so forth) led to more or less severe attacks of fever, vomiting, and diarrhœa. The general decline was very rapid, when it was decided to give three subcutaneous injections, one every other day, of 8, 16, and 30 minims of sterilised cow's milk. The third injection was followed by a general and local reaction of the most violent description, with rigors, vomiting, and rapid alternations of temperature; but from this moment the infant tolerated milk by the mouth in progressive doses of 5, 10, and 30 g. a day, eventually reaching 300 to 350 g. The resumption of milk feeding brought about a rapid increase of weight of more than 2 kg., and a notable amelioration in the general condition. At the moment the baby will tolerate any sort of milk.

June 5th.

Public Health.

REPORTS OF SCHOOL MEDICAL OFFICERS.

Aberdeen.—In the City of Aberdeen the number of children attending the public schools of all kinds during the year ending June 30th, 1919, was 30,879, of whom 26,093 were pupils at the 28 primary schools. Of these, 9335 were systematically examined in detail. An interesting table is given by Dr. George Rose, the school medical officer, showing the average heights and weights of the children in the year under review as compared with similar observations in 1912–13, before the war. Amongst boys, in two of the three age-groups (5 and 7 years), there was found in 1918–19 to be an increase in the average height as compared with the corresponding groups in 1912–13, the increases in these groups averaging 0·4 and 0·2 inch respectively at the earlier ages of 5 and 7 years; while at 13 years old the average height was 0·2 inch less than in the pre-war year. Among girls there was a decrease in average height in the 5 and 7 year age-groups, the average decrease being 0·2 inch in each group; while in the 13-year children the average height was exactly the same as in the pre-war year. As regards weight, among the boys there was an improvement in each group, the increase being 0·4, 0·3, and 0·4 lb. respectively. The girls, on the other hand, showed a lessened weight in each group, the average drop being 0·1, 0·2, and 0·5 lb. in the three age-periods respectively. These observations apply to 9261 children examined in 1919, and presumably a somewhat similar number in 1913. If similar comparisons were made throughout the country valuable data would be obtained as to the influence of war conditions on the nutrition of the juvenile population:

> "There seems no reason for believing that the diminished consumption of sugar has been prejudicial to health, or that the margarine, which contains a certain amount of animal fat, is not a satisfactory substitute for butter. As the present heights and weights of children compare favourably with those of pre-war times, we may conclude not only that the food allowance for children was sufficient in the amount of proteids, carbohydrates, and fats, but that there was in it a sufficient amount of vitamine, which is imperative for the health, nutrition, and growth of the young."

The condition as regards nutrition was considered to be either "average" or "above the average" in 94·5 per cent., and this in spite of the fact that from one to four decayed teeth were present in 60·2 per cent., and in 27·9 per cent. there were as many as five or more decayed. Delicate children, such as those suffering from malnutrition or anæmia, or non-infectious tuberculous disease, have been sent to the Linnmoor Home, where they have a wide expanse of moor in which to play, and also to find shade and shelter. It was found that a stay of four to eight weeks generally added between 3 and 4 lb. weight to each child—as good a result as may be obtained by a six months' stay in an ordinary open-air home. Great improvement has taken place in the cleanliness of the Aberdeen school-children, which formerly had been very defective; and not only the children, but the parents and the homes have been brought up to a decent level in this regard. The number of verminous children in the group of poorer schools has been reduced from 15·3 per cent. to 1·5 per cent., and actual dirtiness of the skin has fallen from 15·7 to 0·9 per cent. It is evident that the educational and medical authorities of Aberdeen have effected immense improvements in the last few years, and there is good reason to believe that these improved conditions will continue.

Bootle.—The county borough of Bootle has 12,993 children on the roll in the council and denominational schools, with an average attendance of 11,320. During the calendar year 1919 3683 children were inspected at the routine examinations. The number with some physical defect reached the very high percentage of 72·7, the most numerous ailments found being defective vision and squint (13·4), enlarged tonsils (7·2), lung disease (7·1), malnutrition (6·8), adenoids (2·2), and organic heart disease (2·2). The total percentage of defects, high as it is, was less than in any of the preceding four years, when it varied between 80·1 in 1918 and 87·5 in 1916; but was more than in 1914, when it was only 66·5. Dr. Allen Daley, the school medical officer and medical officer of health, draws attention in this report to what he very rightly calls "the alarming increase in the number of unvaccinated school children." The entrants found to be unvaccinated in 1914 were 9·7 per cent. of the total number examined; the proportion has increased to 12·6 in 1918 and 14·1 in 1919. The responsibility for this neglect lies in the first instance upon the parents; but the local vaccination authority cannot escape some share in this. Ultimate responsibility rests with the legislature. A comparison of the heights and weights of the children in the year under report with similar observations, before the war, in 1913 shows that amongst boys there was a very slight increase in the average height in the 5-year old group (103·8, compared with 103·6 centimetres), that of the 12-year old group (135·5) being slightly less than in the former year (136·1). Among girls there was a similar but larger increase in the 5-year olds (103·3, compared with 102·4 centimetres), but a decrease in the 12-year olds (137·3, compared with 138·0 centimetres). As regards weight, the 5-year old boys averaged 17·5 kilos (compared with 17·7 in 1913), but the 12-year old boys averaged 31·6, compared with 31·1 kilos in 1913. Among girls, the 5-year olds averaged 17·2 (compared with 17·1) and the 12-year olds 32·2 (compared with 32·5 kilos.). It cannot be said that there was any definite deterioration of health or nutrition owing to the special circumstances of the times. Dr. Daley draws attention to the fact that a considerable number of children for whom spectacles have been prescribed and obtained are found at inspection not to be wearing them. They are left at home, or broken. He recommends that class teachers should make lists of their scholars who ought to wear glasses, and insist upon these being worn. No one wishes to add to the already heavy and manifold responsibilities of the class teachers, but there can be no doubt that their influence and authority would be of the greatest use in securing the desired result. The clinic for remedial exercises, massage, and electrical treatment, under Mrs. Cartwright, principal of the Liverpool School of Massage, continued and greatly increased its good work; the number of children treated rose from 71 in 1918 to 178 during the year under review. Instruction in breathing exercises after throat and nose operations, and chest expansion generally, and the treatment of stammering and chronic ear discharge, are amongst the activities of this excellent institution. The sanitary authority propose to build an annexe to the Maghull Sanatorium for children in the pre-tuberculous condition; and sanction has been given, in response to a request by the Maternity and Child-Welfare Committee of the Corporation, for the treatment of children under school age, whose parents cannot afford private medical attention. This application of the principle, *obsta principiis,* is likely to prove economical in the long run.

URBAN VITAL STATISTICS.

(Week ended June 5th, 1920.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 18 million persons, the annual rate of mortality, which had been 13·8, 13·2, and 12·8 in the three preceding weeks, further declined to 11·6 per 1000. In London, with a population of nearly 4½ million persons, the annual rate was 11·0, or 1·1 per 1000 below that recorded in the previous week, while among the remaining towns the rates ranged from 1·7 in Acton, 4·3 in Eastbourne, and 5·5 in Leyton to 18·9 in Carlisle, 20·5 in Barrow-in-Furness, and 20·7 in West Hartlepool. The principal epidemic diseases caused 220 deaths, which corresponded to an annual rate of 0·6 per 1000, and comprised 69 from measles, 54 from infantile diarrhœa, 41 from whooping-cough, 38 from diphtheria, 14 from scarlet fever, and 4 from enteric fever. Measles caused a death-rate of 1·5 in Rhondda and 2·0 in Great Yarmouth, but the mortality from the remaining diseases showed no marked excess in any of the towns. The deaths attributed to influenza, which had been 216, 211, and 188 in the three preceding weeks, further fell to 148, and included 42 in Sheffield, 19 in London, 13 in Manchester, and 6 in Liverpool. There were 1747 cases of diphtheria and 1635 of scarlet fever under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 1797 and 1703 respectively at the end of the previous week; one case of small-pox was notified and admitted to hospital during the week. The causes of 30 of the 3962 deaths in the 96 towns were uncertified, of which 6 were registered in Birmingham, 4 in Liverpool, and 3 each in London and Blackpool.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2½ million persons, the annual rate of mortality, which had declined from 18·4 to 14·2 in the four preceding weeks, further fell to 13·6 per 1000. The 289 deaths in Glasgow corresponded to an annual rate of 13·5 per 1000, and included 10 from measles, 7 from small-pox, 4 each from whooping-cough and infantile diarrhœa, and 1 each from typhus, scarlet fever, and diphtheria. The 93 deaths in Edinburgh were equal to a rate of 14·2 per 1000, and included 2 from diphtheria and 1 from infantile diarrhœa.

Irish Towns.—The 149 deaths in Dublin corresponded to an annual rate of 18·7, or 0·4 per 1000 below that recorded in the previous week, and included 11 from whooping-cough, 3 each from measles and infantile diarrhœa, and 1 from scarlet fever. The 116 deaths in Belfast were equal to a rate of 14·6 per 1000, and included 3 from infantile diarrhœa, and 2 each from enteric fever, whooping-cough, and diphtheria.

Dr. J. H. Conyers has been appointed a Member of the Executive Council of the Colony of British Guiana.

The Services.

ARMY FEES FOR CIVILIAN DOCTORS.

CIVILIAN medical practitioners giving professional attendance to soldiers will now be paid day fees ranging from 3*s.* 9*d.* to 7*s.* 9*d.* according as the distances travelled vary from under one mile to under five miles. Night fees for similar distances will range from 5*s.* 3*d.* to 13*s.* 3*d.* Extra fees will be allowed for distances over five miles, but the limit for an ordinary visit will be £1.

ARMY MEDICAL SERVICE.

Col. R. J. Blackham is placed on half pay.

ROYAL ARMY MEDICAL CORPS.

Major R. V. Cowey to be acting Lieutenant-Colonel.

The undermentioned temporary Captains relinquish the acting rank of Major: M. C. Gardner, F. P. Joscelyne, R. S. Morshead, J. W. McKinney, D. B. I. Hallett, T. L. Hardy.

Capt. J. Y. Moore retires, receiving a gratuity, and is granted the rank of Major.

Temp. Capt. R. A. Warters relinquishes his commission on transfer to Indian Medical Service.

A. W. D. Magee to be temporary Captain.

Officers relinquishing their commissions:—Capt. J. W. G. H. Riddel (granted the rank of Major). Temp. Capts. F. E. Reynolds (Lieutenant, 2/1 Yorks Hrs. Yeo., T.F.), F. G. Bell (granted the rank of Major), J. W. Clyne, O. S. Kellett, and J. J. A. Sherry (retain the rank of Captain). Temp. Hon. Lieut. A. H. Chu (retains the rank of Lieutenant).

GENERAL RESERVE OF OFFICERS.

Late Captains, R.A.M.C., to be Majors: J. W. G. H. Riddell, J. Y. Moore, A. L. Aymer, W. T. Hare.

SPECIAL RESERVE OF OFFICERS.

Capt. W. F. McLean relinquishes the acting rank of Lieutenant-Colonel.

TERRITORIAL FORCE.

Capt. W. A. Valentine to be Major.

The undermentioned Majors resign their commissions and retain the rank of Major: W. F. McAllister-Hewlings and P. McK. Terry.

The undermentioned Captains resign their commissions and retain the rank of Captain: P. N. Creagh, S. Wyard, P. T. Catto, J. G. Hill, W. Fitzpatrick, A. Greene, J. G. McKinlay.

1st Scottish General Hospital: Capt. A. W. Falconer resigns his commission and is granted the rank of Lieutenant-Colonel.

ROYAL AIR FORCE.

Medical Branch.—Flying Officers J. Kyle and C. T. O'Neill to be Flight Lieutenants.

The undermentioned are transferred to the unemployed list: Capts. J. W. Healy, F. L. Dickson, and Lieut. F. Gill.

Dental Branch.—Flight Lieut. C. L. Colbran to be acting Squadron Leader whilst employed as Squadron Leader.

J. H. W. Fitzgerald is granted a temporary commission as Flight Lieutenant.

The King has granted permission to Temp. Capt. E. B. Jones, R.A.M.C., to wear the Cross of Officer of the Order of St. Sava, conferred upon him by the King of the Serbs, Croats and Slovenes, in recognition of his services to the Serbian wounded in 1914–1915, under the auspices of the Serbian Relief Fund.

INDIA AND THE INDIAN MEDICAL SERVICE.

Lieut.-Col. A. W. R. Cochrane, civil surgeon Agra, to be Principal, Medical School, Agra, vice Lieut.-Col. G. J. O'Meara. Department Major D. Munro, promoted acting Lieutenant-Colonel, has been granted leave. Major H. B. Steen officiates as Professor of Surgery, Medical College, Calcutta, vice Lieut.-Col. R. P. Wilson, granted leave. Major J. C. G. Kunhardt acts as Assistant Director, Bombay Bacteriological Laboratory. Major-Gen. Jennings has been appointed additional Member of Bombay Council. Medical Department Major H. H. Thorborn is posted Administrative Medical Officer, Quebla. Major C. L. Dunn, sanitary commissioner, has been granted long leave. Dr. D. D. Pandra, deputy sanitary commissioner, officiates Sanitary Commissioner, United Provinces, while Major C. L. Dunn is on leave. Lieut. F. E. Knight, on return from military duty, has been appointed Deputy Superintendent, Central Lunatic Asylum, Berhampore, Murshidabad. Capt. R. B. Lloyd, resident medical officer, Medical College, Calcutta, officiates as Chemical Examiner and Professor of Chemistry, vice Capt. Bose, granted leave. Major F. A. Barker officiates as Civil Surgeon, Port Blair, vice Major Murray. Lieut.-Col. Sing has been appointed to succeed Dr. Lankaster as Assistant Director, Nizam's Medical Services.

FOREIGN DECORATIONS.

Belgian.

Médaille du Roi Albert.—Col. G. A. Moore, C.M.G., D.S.O.

French.

Médaille d'Honneur avec Glaives (en Vermeil).—Col. A. D. Ducat, D.S.O., A.M.S. (T.F.); Capt. M. W. Paterson, O.B.E., M.C., R.A.M.C. (S.R.); Capt. R. P. Pollard, M.C., R.A.M.C. (T.F.); Capt. D. J. Scott, O.B.E., M.C., R.A.M.C. (T.F.).

Médaille des Épidémies (en Argent).—Temp. Capt. (acting Major) J. R. Anderson, R.A.M.C.

Roumanian.

Order of the Star of Roumania (with Swords).—Chevalier: Capt. D. C. L. Fitzwilliams, C.M.G., R.A.M.C. (T.F.).

Correspondence.

"Audi alteram partem."

THE STANDARDISATION OF COLOUR PERCEPTION.

To the Editor of THE LANCET.

SIR,—Mr. Herbert Parsons, in his letter to THE LANCET of June 5th, disclaims any intention to depreciate the work of Dr. Edridge-Green. But it is particularly noticeable that he has but little to say in its favour. Indeed, in the last paragraph the threat is implied of an intended tilt with Dr. Edridge-Green and his theories. Among the numerous psychologists, physiologists, ophthalmic surgeons, and others who have convinced themselves of the reality and accuracy of Dr. Edridge-Green's work no less than to the 100 per cent. of those who have failed to prove that any of his statements are wrong, the contemplated contest will doubtless be hailed as a welcome diversion in one of the most difficult of the by-paths of science. But Dr. Edridge-Green is a doughty champion; in the course of the 35 years' study of his subject he has fortified himself with an armour of research which has ensured for him victory in every contest in which he has been engaged.

It seems rather late in the day for Mr. Parsons to complain of the "judicial attitude" having been lost sight of in the reviews which have appeared of Dr. Edridge-Green's recent book. The ground of his complaint is that he thinks the author has been unduly praised for his work. Had this "judicial"—and not prejudicial—"attitude" been assumed during the many years in which Dr. Edridge-Green has struggled to gain a hearing for his theories, by the Royal Society and its clique of his opponents, the praise would have appeared not novel but natural. Again, if the Board of Trade lantern, in Mr. Parsons's opinion, is better than Dr. Edridge-Green's colour-perception lantern, how is it that the former should have been rejected and the latter chosen by the Royal Navy as the best? The fact, also, that Dr. Edridge-Green's lantern has been adopted by the navy of the United States, the Norwegian Navy, the India Office, and numerous other bodies, is obviously significant. Surely such a galaxy of support in favour of this lantern rather discounts Mr. Parsons's preferential opinion of the lantern in use by the Board of Trade. It is a curious argument to advance against Dr. Edridge-Green's lantern that it requires skilled knowledge to use it. Nevertheless, it exposes, I think, the motive of your correspondent's letter.

I am, Sir, yours faithfully,

Wimpole-street, W., June 7th, 1920. PERCY DUNN.

THE INDUSTRIAL SETTLEMENT FOR THE CONSUMPTIVE.

To the Editor of THE LANCET.

SIR,—While admiring in no small degree the distinguished preliminary work upon village settlements and industries which has been done at Papworth, I feel bound to disagree most heartily with the terminal portion of the article by Professor Sir G. Sims Woodhead and Mr. P. C. Varrier-Jones, which appeared under the above title in your issue of May 8th. The following lines appear:—

> "It may be, indeed it has been, suggested that the village settlement is an expensive method of attaining an end that might be achieved by simpler and less costly means. Is it not possible, it is asked, and would it not be equally effective, to provide workshops in town where, under a special arrangement, these consumptives may work and earn their living? Emphatically, No!"

This, I take it, is a direct condemnation of the scheme I outlined in your issue of Feb. 21st, under the heading "The Municipal Workshop," and is totally unjustified. In that article I outlined a scheme of local workshops, together with active home education, to provide for the complete convalescence of the post-sanatorium cases for whom no colony can exist and for whom ordinary industrial employment constitutes a practical death warrant. No single mode of campaign can rid us of consumption. The sanatorium, with its promised blessings, has proved to be but a link in the chain. Do not let us fall into the same trap with the village settlement and spend fortunes, which the country can ill afford, without a prospect of benefiting the community at large. The projected ten colonies for £1,000,000 will hold, roughly, 2000 ex-soldiers. What is to become of the other 38,000? Dr. N. D. Bardswell tells us that 60 per cent. of those in his area are already dead, and the rest will share the same fate before these settlements can be built. What provision can there be for 300,000 civilians? Must they be condemned to unemployment because they live in towns? Emphatically, No!

The special workshop, capable of indefinite expansion at small cost, near the patients' own homes, is the only method which can hope to cope with the numbers needing this assistance. We have yet to see that the houses, under improvement by education, will be materially detrimental to success. In Birmingham the mortality for men aged 35–45, being twice as great as the females of the same age, relieves the housing of most of the blame. As much will be done by education and improvement of social standards as by new housing.

Again, the town-dweller of the class catered for cannot be given country instincts at will. The craving for town life is irresistible, and many will return. Tuberculosis is a "social disease," and must be fought in its stronghold, the social life of the community. We need education and improved industrial conditions, with special provision in the form of "municipal workshops" for tuberculous labour, now almost entirely wasted.

I am, Sir, yours faithfully,

F. STANLEY TINKER, B.A., M.B.,
B.C., M.R.C.S., L.R.C.P.,
Tuberculosis Officer, North-East Surrey.

Wimbledon, June 3rd, 1920.

AGE AND VENEREAL INFECTION.

To the Editor of THE LANCET.

SIR,—The appended figures were given to me by a friend who did a very great amount of good work amongst V.D. patients as a Y.M.C.A. leader in France and later with the army of occupation on the Rhine. Several points are of special interest: (1) The early ages at which illicit coitus may and does begin. (2) The sharply defined maximum at the age of 18. (3) The rapid fall between the age of 18 and the age at which the men as a general rule get married. The cases were not picked and represent a series of 300 odd V.D. patients drawn from all parts of the rank and file of the B.E.F. Unfortunately, I have no figures of the exact ages of the patients nor any data of their marriages, &c. It is, however, thought that further research on these or similar lines might discover new means with which to combat and prevent venereal disease from the educational and moral points of view.

I am, Sir, yours faithfully,

G. G. JOHNSTONE, M.D.

Hampstead Way, N.W., June 7th, 1920.

Appended Table showing Analysis of 296 Cases at a Base V.D. Hospital in France.

A.	B.	C.	A.	B.	C.	A.	B.	C.

17	39	13·0						

Col. A indicates the ages at which the patients stated that they first had illicit sexual intercourse.

Col. B gives the numbers going wrong for the first time at the different ages.

Col. C gives the percentages of the whole going wrong for the first time at the different ages.

THE SURGICAL TREATMENT OF UTERINE AND VAGINAL PROLAPSE

To the Editor of THE LANCET.

SIR,—In answer to Dr. Blair Bell's reply in THE LANCET of June 5th to my letter published in the issue of May 15th, I beg to point out that Dr. Blair Bell appears to labour under some erroneous notions. He says I was subversive without being destructive, and apparently thinks I wished to be destructive. But I believe any unprejudiced reader of my letter will see that instead of being destructive, I strove to be constructive, and, indeed, strove to elucidate the riddle of how plastic visceral procedures are of value in the treatment of prolapse.

Another erroneous notion, which Dr. Blair Bell appears to hold, is that my impressions of prolapse are nebulous. May I assure Dr. Blair Bell that my "impressions" of prolapse are anything but nebulous. I have not laboured since 1908 at this subject without obtaining some clear and coherent ideas concerning it, and, certainly, I am prepared to argue with Dr. Blair Bell on it It is true he may not understand my words, my "strange and obscure phrases," and my argument, but I cannot help that. If he wants to learn—and he tells us he is still a student—he must try to understand, in spite of its being "tedious" and "nauseous" If he wants to ignore my work, he can do so, and since he is so satisfied with his treatment of prolapse, there is no reason why he should pay attention to me. Critical letters in THE LANCET, I take it, are not merely inserted for the benefit of a writer of an article, but for the main body of your readers who may happen to be interested in the subject, and may be led astray by the *couleur de rose* of an author.

Judging from his letter, it appears to me that Dr. Blair Bell's own ideas on prolapse are somewhat nebulous He does not seem to understand the meaning of the word "floor", or, if he supposes that the utero sacral and utero pubic ligaments, with other connective tissue attachments of the cervix, form a floor for the pelvis he is, I submit, hopelessly in error. If he really regards "the musculature of the pelvic outlet," with which he is so "concerned," the real floor of the pelvis, why does he attribute such importance to these other structures, and how does he conceive operations on them act in curing prolapse? He cannot run with the hare and hunt with the hounds. Nor does Dr. Blair Bell seem to understand the meaning of the word "congenital." He is quite at liberty to call solitary extrusion of the cervix occurring in adolescent and older virgins "congenital prolapse", he may call it what he likes But the question is whether thinking men will accept his teaching Has he any evidence that these cases are congenital? If so, why does he not publish it?

I offered in my letter an original and new idea as to the way plastic visceral procedures are of service in prolapse But Dr. Blair Bell appears not to understand this idea. He refers to it ironically in passing, its basis is presented in "another strange phrase." He apparently does not want ideas; he wants "facts and figures" I object to this attitude altogether. The value of statistics is well known; they can be "wangled" to show anything. What is required, I submit, is not facts and figures, but an interpretation of facts and figures In his lecture Dr. Blair Bell gave us plenty of facts but no interpretation of them; as to figures, we have a 99 per cent. cure out of 400 cases But, concerning these, we have some interpretation—that many patients get well, whatever the treatment.

In conclusion, may I express the pious hope that Dr. Blair Bell may attain his ambition of learning "how to reach the 'zenith'" of the surgical treatment of prolapse? It has been a long and tedious business getting as far as we have, as students of its history know, and men are still dubious As regards my own ideas of advance—my "methods and figures"—Dr. Blair Bell may rest assured they will be published in my own good time.

I am, Sir, yours faithfully,

Rugby, June 5th, 1920 R. H. PARAMORE.

THE FOUNDATIONS OF PITY.

To the Editor of THE LANCET.

SIR,—Your interesting article on the Prophylaxis of Shell Shock in THE LANCET for May 29th attributes the drawing of the distinction between pity as an emotion and pity as a motive to Robert Louis Stevenson. Dr. John Brown, however, in his immortal "Rab and His Friends" (published in 1858), in reference to the students running to the operating theatre to get good seats for witnessing the removal of poor Ailie's breast, says —

> 'Don't think them heartless they are neither better nor worse than you or I they get over their professional horrors, and into their proper work, and in them pity, as an *emotion*, ending in itself or at best in tears and a long drawn breath, lessens,—while pity, as a *motive* is quickened, and gains power and purpose It is well for poor human nature that it is so'

I am, Sir, yours faithfully,

Harley street, W, June 4th, 1920 J. DUNDAS GRANT.

Medical News.

EPSOM COLLEGE WAR MEMORIAL FUND.—A meeting of old Epsomians interested in the war memorial will be held at the offices of the school, 49, Bedford square, W.C, on Thursday, June 24th, at 5 P.M. 1. To discuss the immediate erection of a tablet of commemoration, as it is not possible to begin the chapel rebuilding for some time. 2. To meet the committee specially appointed to collect subscriptions and donations 3 To decide on the form which the tablet is to take

UNIVERSITY OF CAMBRIDGE.—The sum of £165,000 has been received for the building and maintenance of a department of biochemistry on a site provided by the University, and for the endowment of a chair and a readership The benefaction is derived from the residual estate of the late Sir William Dunn, who appointed the directors of the Commercial Union Assurance Co. as trustees for its disposal

UNIVERSITY COLLEGE, LONDON. A DEPARTMENT OF APPLIED STATISTICS —The new buildings presented by Sir Herbert Bartlett to University College, London, to serve as a Department of Applied Statistics, were opened formally last week by the Minister of Health Dr Addison, in declaring the buildings open, emphasised the fact of the value of applied statistics, and implied that many of our social figures were in an incomplete and unsatisfactory condition He pointed out that Professor Karl Pearson, as Galton professor, had, with the assistance of his staff, turned out through the department admirable services during the war, especially to the Department of Munitions, and he made a strong appeal for money to equip adequately the splendid premises due to Sir Herbert Bartlett's generosity The many directions in which the use of applied statistics is necessary frequently escape the notice of medical men, who regard this scientific work, in relation to theirs, as being mainly concerned with the figures of mortality, of census taking, and of disease incidence, whereas the study of, for example, anthropology and heredity equally demand accurate mathematics

STATISTICS FROM MATERNITY INSTITUTIONS AND FROM CHILDREN'S HOMES AND HOSPITALS.—The Minister of Health is demanding certain information from all institutions receiving resident children under 5 years of age The details required include the number of cases admitted, average duration of stay, reasons for admission, condition on discharge, number of cases of infectious disease and number of deaths, with date and cause Immediate information of all deaths from epidemic diarrhœa is to be given In regard to maternity homes and hospitals the information is to include the number of cases admitted, the average duration of stay, the number of cases delivered by, respectively, midwives and by doctors The cases for which medical assistance was sought by the midwife are to be classified according to the reasons for appealing for assistance and the period at which this was required The number of cases of puerperal sepsis, of a rise of temperature above 100 4° F for 24 hours, with rise of pulse rate, of ophthalmia neonatorum, of "inflammation of the eyes, however slight," of artificial feeding, and of maternal and fœtal deaths, have all to be recorded, with details of causes, results of treatment, and in fatal cases, of post mortem findings The Minister also requires immediate and detailed information of every case of maternal mortality occurring in the institution, or due to illness contracted in the institution, and every case of notified puerperal fever.

THE Board of Education has notified that the Draft, dated March 19th, 1920, of the Board of Education (Higher Education, Medical Inspection and Treatment) Regulations, 1920, has been published for the required period, and has now been confirmed by the Board without amendment. The Draft now becomes the Board of Education (Medical Inspection and Treatment, Higher Education) Regulations, 1920, dated May 20th, 1920, and copies can be purchased through any bookseller (price 1*d.*), or directly from H.M. Stationery Office, Imperial House, Kingsway, London, W.C. 2 (price by post 1½*d.*).

LONDON DERMATOLOGICAL SOCIETY.—The annual general meeting of this society will be held at 4.30 P.M. on Tuesday, June 15th, at St. John's Hospital, 49, Leicester-square, W.C., when the election of officers will take place. The nominations of the council for principal offices are as follows: President, Dr. R. Prosser White; honorary treasurer, Dr. W. Knowsley Sibley; honorary secretary, Dr. Maurice G. Hannay. At 4.45 P.M. clinical cases will be shown.

INDIAN MEDICAL SERVICE DINNER.—The annual dinner of the Indian Medical Service was held at the Trocadero Restaurant on Tuesday, June 8th. The chair was taken by Major-General G. F. A. Harris, C.S.I., and more than 70 members were present. There were no set speeches, but Colonel R. H. Elliot and General Sir Havelock Charles spoke on the subject of the suggested alterations in the conditions in the Service, and pointed out that though the improvements were not all that might be desired, yet they were all that could be obtained at the present time, and that they constituted an enormous advance on the conditions now obtaining. Stress was laid on the services in this connexion of the *British Medical Journal* and its editor, Dr. Dawson Williams. The following members were present:—

Major-Generals: Sir R. Havelock Charles, T. Grainger, P. Hehir.

Colonels: C. W. Carr-Calthrop, J. Crimmin, V.C., Sir P. J. Freyer, C. M. Goodbody, D. E. Hughes, G. B. Irvine, W. H. Ogilvie, J. J. Pratt.

Lieutenant-Colonels: A. Alcock, W. G. P. Alpin, J. Anderson, W. R. Battye, D.S.O., A. T. Bown, R. Bryson, J. T. Calvert, R. H. Castor, D. G. Crawford, C. Duer, R. H. Elliot, F. F. Elwes, S. C. Evans, A. B. Fry, G. H. D. Gimlette, T. A. Granger, H. Greany, A. W. M. Harvey, J. G. Hulbert, C. H. James, S. P. James, J. Lloyd Jones, J. G. Jordan, R. W. Knox, Clayton Lane, S. Little, T. R. Mulroney, R. A. Needham, A. H. Nott, S. Browning Smith, R. F. Standage, R. Steen, T. H. Symons, W. H. Thornhill, J. H. Tull Walsh, Ellacott L. Ward, J. W. Watson, H. R. Woolbert, H. G. L. Wortabet, A. C. Younan.

Majors: W. M. Anderson, A. Cameron, S. Chuckerbutty, R. G. G. Croly, J. Forrest, C. A. Godson, E. T. Harris, A. H. Napier, E. S. Phipson, M. Purvis, J. J. Robb, W. C. Ross, W. R. J. Scroggie, F. E. Wilson.

Captains: U. J. Bourke, W. B. Keyworth, N. N. G. C. McVean, J. G. B. Shand, H. Stott.

The guests were the editors of the *British Medical Journal* and *The Lancet*.

ROYAL NAVY MEDICAL CLUB: ANNUAL DINNER.—The annual dinner of the Royal Navy Medical Club took place at the Trocadero Restaurant on May 28th. The Medical Director-General of the Navy, Surgeon Rear Admiral Sir Robert Hill, K.C.M.G., C.B., C.V.O., presided. The guests of the evening were Sir George Lenthal Cheatle, K.C.B., C.V.O., and Surgeon Commander E. J. Steegman, O.B.E., R.N.V.R. The following members were present:—

Surgeon Rear Admirals: P. W. Bassett-Smith, C.B., C.M.G.; W. Bett, M.V.O.; J. Chambers, C.M.G.: G. A. Dreaper; D. T. Hoskyn; Sir D. J. P. McNabb, K.B.E., C.B.

Surgeon Captains: O. W. Andrews, C.B.E.: C. M. Beadnell; E. C. Cridland; J. F. Hall, C.M.G.; M. H. Knapp; F. W. Parker, O.B.E.; E. A. Penfold, D.S.O.; W. H. S. Stalkartt.

Surgeon Commanders: E. L. Atkinson, D.S.O.; A. R. Bankart, C.V.O., K.H.P.; G. D. Bateman; C. T. Baxter; K. D. Bell; R. St.G. S. Bond; C. J. E. Cook; F. J. A. Dalton, C.M.G.; J. S. Dudding; J. H. Fergusson; A. F. Fleming, D.S.O.; A. Gaskell, C.B., O.B.E.; R. Hughes; W. W. Keir, C.M.G.; H. A. Kellond-Knight; R. H. McGiffin, O.B.E.; P. M. May; N. S. Meiklejohn, D.S.O.; J. O'Hea; J. H. Pead; B. P. Pick; S. Roach; M. L. B. Rodd, O.B.E.; R. A. Ross; J. Stoddart; E. Sutton, C.M.G.; J. A. Thompson; A. J. Wernet.

Surgeon Lieutenant Commanders: J. H. B. Martin; F. L. Smith; H. E. R. Stephens, O.B.E.

CONFERENCES ON MATERNITY AND CHILD WELFARE.—In connexion with the Baby Week celebrations conferences will be held at Leeds on June 30th, at Manchester, Brighton, Bradford, and Wrexham early in July, and at Crewe in September. The subjects to be discussed will include (*a*) Widows' Pensions; (*b*) The Home and its Substitutes for the Care of Young Children; (*c*) Infant Welfare Work; (*d*) The Decay of Parenthood. Local health, sanitary, maternity and child welfare, and Poor-law authorities throughout the country, as well as voluntary organisations, are cordially invited to appoint delegates to attend the conferences, and all persons interested will be welcomed. Further particulars and tickets (1*s.*) will be forwarded on application to Miss Halford, secretary National Association for the Prevention of Infant Mortality, 4, Tavistock-square, London, W.C. 1.

DOWN TUBERCULOSIS SANATORIUM.—As a result of the Local Government Board's recent inquiry into the application of Down County Council for sanction to borrow £27,000 for the purpose of purchasing Craigavon as a sanatorium for consumptives, the County Council has received from the Board a letter stating that:—

> "In the Board's view the main issue raised in the inquiry turns on the conflict of public interest—on the one hand of the need of county Down patients for tuberculosis treatment, and on the other of the welfare of Belfast. Seeing that the Belfast Corporation as the local authority have publicly, and on grounds which were not refuted, represented the scheme of the Down County Council as injurious to the development and progress of the county borough, the Board can only come to the conclusion, though with some regret, that the proposition is not one to which they should afford facilities by consenting to the application of a loan."

THE SALARIES OF SCHOOL MEDICAL OFFICERS.—The Devon Education Committee recently advertised in the daily press for a school medical officer at a salary of £400 to £500 per annum. There was one applicant, who received the appointment, but within a few hours he withdrew from the post. A "locum tenens" was then appointed at a salary of 10 guineas weekly. At the last meeting of the committee a discussion took place upon the matter, some of the members wishing that the usual salary of £500 to £650 a year should be given to the school medical officer, but eventually it was decided to ask the present "locum" if he would take the appointment permanently at the salary of £400 to £500 per annum. The county medical officer of health, however, informed the committee that its offer would be quite useless.

SOUTHMEAD INFIRMARY, BRISTOL.—The Guardians' Infirmary at Southmead has been in the hands of the army authorities since its completion in August, 1914. The guardians had not previously been using the building, which was actually finished only after the army authorities had entered into possession. The medical staff now arranged for the institution is as follows: Medical superintendent, Mr. R. H. Norgate, for many years medical officer at the Stapleton and Eastville Institutions; two assistant medical officers about to be appointed. The guardians have also arranged, as a commencement, to appoint as visiting or consultant medical officers: Physician, Dr. J. A. Nixon; surgeon, Dr. H. G. Kyle; physician for children's diseases, Dr. O. C. M. Davis; surgeon for diseases of the ear, nose, and throat, Dr. E. Watson-Williams; dental surgeon, Mr. George F. Fawn.

PROPOSED AMALGAMATION OF BRISTOL HOSPITALS.—The present position of the plans for union of the Bristol hospitals is that, although some progress has been made, the uncertainty as to the attitude of the General Hospital prevents any active steps being taken. This uncertainty will probably be resolved before long, as the hospital governors are called for a meeting in a few days' time. The following resolution, passed at a special meeting of the Hospital Committee on May 18th, will be laid before the governors:—

> That the committee of the Bristol General Hospital, after careful consideration and full discussion with the members of the honorary staff, record their opinion that, in view of the uncertainty of the provisions of the Bill which it is understood is now being prepared by the Ministry of Health, they cannot see their way to accept the suggested scheme of amalgamation of the Bristol hospitals, particularly having regard to its proposal for the immediate and irrevocable transfer of all the buildings, investments, and other assets to a new authority. The committee will, however, gladly consider any proposals for coöperation or coördination which are calculated to benefit the sick and improve medical education.

This resolution has an air of finality about it, but since it was passed two things have happened which may perhaps furnish a foundation for some discussion. The first is the publication of the interim report of the Medical Consultative Council. This removes some of that uncertainty as to the future of hospitals which the resolution expresses, and shows (with peculiar force, inasmuch as Bristol is the "teaching hospital" centre of the Consultative Council's illustrative map) that the supreme position in the projected grouping of hospitals will go to that one which is closely allied to a medical school. The second event which bears upon the resolution is the acceptance by the Children's Hospital of the amalgamation scheme, on condition that its buildings are used for a children's hospital and not diverted to another purpose. On the one hand, this may be regarded by the General Hospital as a precedent which it might usefully adopt—i.e., of joining the proposed amalgamation on condition that its buildings and invested capital were reserved for those purposes for which they were originally accumulated. On the other hand, the union of the Royal Infirmary and the Children's Hospital will in any case enable Bristol to play the part of "teaching hospital" centre to the South-West of England, for the two hospitals together provide over 500 beds in close contiguity with the University, and the General Hospital may feel that since this purpose is thus provided for, it has no need to aspire to any position above that of the "secondary health centre" of Lord Dawson's report.

The Incorporated Society of Trained Masseuses—The annual Members' Conference will be opened on June 24th at Mortimer Hall, Mortimer street, London, by Professor Arthur Keith

Overseas Nursing Association—The annual meeting of this association will be held on Thursday, June 24th, at 3 30 P M , at Norfolk House, St James's square S W by permission of the Duchess of Norfolk, when H R H Princess Beatrice will be present Viscount Gladstone will preside over the meeting of supporters

48th General Hospital—The first annual dinner of this unit will take place at the Piccadilly Hotel (Adams' Room), London, W , on June 24th, at 7 30 P M Dinner 21*s* , exclusive of wines Those who intend to be present are asked to communicate at once with Dr B Holroyd Slater, St Luke's Hospital, Bradford

Royal Institution—A general meeting of the members of the Royal Institution was held on June 7th, Sir James Crichton Browne, Treasurer and Vice President, in the chair, when the special thanks of the members were returned for a gift of £1000 in the name of the late Dr Frederick Du Cane Godman, F R S , per Dame Alice Godman D B E

A Great Hospital Closed—In view of the financial position of the National Hospital for the Paralysed and Epileptic, Queen square, W C , the board of management has been obliged to close the in patient department and has directed that no further patients are to be admitted after the current week Notice has been sent to the 144 patients on the waiting list that they cannot be taken in

London School of Clinical Medicine The Seamen's Hospital Greenwich—A course of operative surgery, specially adapted to the needs of general practitioners will be held from June 21st to July 28th, meeting on Mondays, Tuesdays, and Wednesdays at 2 30 P M The inclusive fee for the course is 10 guineas, and applications should be made to the Dean at the Seamen's Hospital, Greenwich, from whom further particulars can be obtained

Ladies Medical Golfing Society—The spring meeting of this society was held at Stanmore Golf Club (by kind permission) on June 3rd The Canny Ryall Cup for the best score under handicap was won by Mrs Grainger Harrison, 95 – 8 = 87, Mrs Farquhar Buzzard being second, 104 – 14 = 90 In the afternoon foursomes *v* bogey were played for prizes presented by Mr Laming Evans The result was a tie between Lady Goadby and Miss Maskelyne, and Mrs Ritchie and Miss Mansbridge at all square The tie was decided on the basis of the first nine holes when Lady Goadby and her partner were 3 up, while Mrs Ritchie and her partner were only 2 up

Parliamentary Intelligence.

HOUSE OF COMMONS

Wednesday, June 2nd

Lieutenant Colonel Sir Raymond Greene asked the Secretary for India whether he was aware that Sister Eleanor M'Loughlin after serving eight years under the India Office as nursing sister at the General Hospital Rangoon Burma was granted one year's medical leave and that whilst returning to England on the ss *Mooltan*, which was torpedoed by the enemy, she lost the whole of her personal effects, and whether the Indian Government, in whose service she was at the time, could grant Sister M'Loughlin some compensation for the loss of her kit, seeing that when her claim was laid before the Reparation Claims Department at the Board of Trade the reply was that nothing could be done until Germany paid —Mr Montagu replied Miss M'Loughlin applied to the Shipping Controller for a free return passage to Rangoon, she did not apply to the India Office for compensation in respect of the loss of her personal effects on the ss *Mooltan* She was, however, granted a free return passage to Rangoon by the India Office and was offered in addition an advance of one month's pay Miss M'Loughlin gratefully accepted these concessions She subsequently resigned her appointment, however, and in view of the exceptional circumstances and as a special concession, the usual period of six months notice for which her agreement stipulated was waived, and she was given a gratuity of two months' pay and her passage from Rangoon to England was paid Miss M'Loughlin has expressed her complete satisfaction with the way in which she has been treated Compensation has not been paid by the India Office in respect of the loss of personal effects by enemy action to officers travelling to or from India, and I regret that I am unable to make an exception in the present case

Thursday, June 3rd

Salaries of Medical Men

Mr Spoor asked the Minister of Pensions whether his attention had been called to an advertisement issued by the Minister of Health inviting medical men to apply for appointments in the Ministry of Health at salaries of £1000 rising to £1400 per annum, with pension rights, &c , whether these appointments were calculated to draw medical officers from the Ministry of Pensions, and whether he could see his way to giving similar salaries and advantages to the medical staff employed by the Ministry of Pensions —Mr Macpherson replied My attention has been drawn to the advertisement in question, which related to certain appointments offered by the Ministry of Health of a permanent character requiring special scientific qualification It is, of course, open to the medical members of my staff to become candidates I cannot undertake to revise the scales of remuneration of the temporary medical service of the Ministry of Pensions which were settled so recently as January of the present year It is not yet possible to forecast the permanent medical arrangements which will be necessary for the purposes of the Ministry —Major Nall Is the right honourable gentleman taking any steps to place disabled medical men in appointments such as this?—Mr Macpherson Oh, yes, quite a large number of disabled medical men are now on the staff

National Insurance Finance

Major Barnes asked the Minister of Health if he would say what amounts had accumulated up to March 31st, 1920, to meet the liabilities arising out of national health insurance and in what hands, what was the estimated annual liability on the Act recently passed, what annual increase would be caused by increasing the benefits in the Act recently passed so as to make them 140 per cent greater than under the Act of 1911, and what annual increase would be caused if the benefits to women were on such increased basis made equal to men?—Dr Addison replied With regard to the first part of the question, the moneys accumulated under the National Health Insurance Acts up to March 31st, 1920, are as follows Investments in the hands of Approved Societies or invested on their behalf in securities selected by them (under Section 56 of the National Insurance Act, 1911) (cost) £29 000 000, investments in the hands of the National Debt Commissioners (under Section 54 of the National Insurance Act, 1911) (cost) £47,500 000, balances of cash in the several National Insurance Funds and in the hands of Approved Societies and Insurance Committees £1,500,000 With regard to the second part of the question, the estimated liability in respect of contributions and State grant arising under the National Health Insurance Act, 1920, for the period July, 1920 to July, 1921, is £36,692 000 of which £14,400 000 will be payable by insured persons £15 350 000 by their employers and the balance—namely, £6,942 000, out of moneys provided by Parliament If sickness, disablement, and maternity benefits were increased by 140 per cent over those provided by the Act of 1911, as suggested in the third part of the question, the corresponding cost on the present actuarial basis of the scheme would be increased by £17 950 000 of which £3 400 000 would fall on the Exchequer and the balance on insured persons and their employers Under the alternative scale for women suggested in the last part of the question, the total cost on the basis indicated would be still further increased by £2,600 000 of which £700 000 would be payable by the State

Monday, June 7th

Pensions Medical Boards

Mr Sturrock asked the Pensions Minister whether he could state how many boards, each consisting of three qualified medical practitioners were sitting daily in the United Kingdom and Ireland, whether the work they discharged was largely routine and could be efficiently done by one qualified man, whether the minimum fees paid to each medical man at present engaged on this work amounted to £1 11*s* 6*d* per day, and whether, having regard to economy he could undertake to alter the system prevailing —Major Tryon (Parliamentary Secretary to the Ministry of Pensions) replied There are at present 455 boards established for the United Kingdom, which sit, not daily, but only as occasion requires For example, the number of sessions held during the week ending May 22nd corresponds with the full time work of 222 boards The work of the boards is by no means routine, but is of a highly technical nature which in very few cases, if any, could be carried out by a single practitioner, and calls for expert examination and diagnosis, followed by consultation between the members in order to secure an equitable assessment The Minister has considered carefully the possibility of reducing the personnel, but he is convinced that any steps in this direction would be against the best interests both of the pensioner and the State, and would fail to achieve any real economy The ordinary fee paid to each member of the board is £1 11*s* 6*d* for each session of two and a half hours I do not regard this fee as in any way unreasonable

Appointments.

Downes, H., M.B., C.M. Edin., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer of Health for the Chard (Somerset) Rural District Council.

Notes, Short Comments, and Answers to Correspondents.

NOTES ON PSYCHOANALYSIS AND PSYCHOTHERAPY.[1]

BY SIR JAMES CRICHTON-BROWNE, M.D., LL.D., F.R.S.,
LORD CHANCELLOR'S VISITOR IN LUNACY.

PART II.*

SUGGESTION is a perfectly legitimate medical weapon, the assistance of which is invoked by every medical man in every prescription, but care must be taken that its nature is clearly understood. This is especially true of hypnosis. In psychotherapy its utility is unquestionable, but its influence is often short-lived, for cases thus treated are admittedly very liable to relapse. When unduly pushed or misapplied it may induce very disastrous consequences. In the war psychoneuroses suggestion has been of conspicuous use, more especially in those cases in which autosuggestion has been at the root of the symptoms. A confident prediction by a sympathetic physician that there is nothing radically wrong and that in a certain definite time, under a certain impressive course of treatment, complete recovery will take place, has often had the happiest effect. *Similia similibus curantur.* What suggestion gave suggestion has taken away. But the results of suggestion are insecure, and backslidings are frequent.

The Doubtful Value of Argument.

Of the value of argument in psychoneurotic cases I am less convinced. The rule used to be that once for all the patient should be encouraged to state fully his mental troubles, and once for all their irrationality should be explained to him, and his objections met; but to recur to the subject again and again and chop logic about it was regarded as bad policy. Lightly held erroneous impressions may be argumentatively jettisoned, but a delusion should not be given belligerent rights. In the presence of the most absolute proof of its absurdity it will stick fast, and, for my own part, I have never known a delusion worn away by controversial methods.

The Anti-repression Method.

To one psychotherapeutic expedient for which great achievements are claimed I should be inclined to demur; this is the anti-repression method, or the upheaval or facing-it-out schema, as it might be called. Repression, which is alleged to have taken so considerable a part in the production and maintenance of the war psychoneuroses, especially of the anxiety neuroses, I confess I do not clearly understand. It is described as "the active or voluntary process by which it is attempted to remove some part of the mental content out of the field of attention, with the aim of making it inaccessible to memory." It is therefore the will to forget, but the will has no such power. It cannot seize a painful or disagreeable thought or feeling by the scruff of the neck and thrust it down into unconsciousness. There is no method by which a person can voluntarily remove from consciousness some part of his mental contents. The will is not a policeman with power to order objectionable memories to move on or to shut them up in the cells below. It is undoubtedly true that by a voluntary endeavour we can modify or divert the stream of images and recollections arising in the mind. When surveying the scene before us we can, under an adequate motive, observe one point and neglect everything else. When engaged in any pursuit it is possible for us to keep out irrelevant thoughts, though arising in the current of association, but this is done, not by any forcible extrusion process but by concentrating attention on the thought or image we desire to observe or study, and leaving all outside thoughts and images to that natural fading towards the vanishing point which takes place when the light at attention is withdrawn. As regards emotional states the one thing practicable is to check or promote that part of their diffusive manifestation that is made up of movements of the voluntary muscles. The suppression of the active movements has a tendency to suppress the nervous currents that incite them. "It is a law of our constitution that the inward wave tends to die away by being refused the outward vent."

There are vehement states of sudden emotional excitement in which it is perhaps better to give free course for a time to their outward display. Anger, grief, or joy may come upon us in such overwhelming force that the current cannot be resisted; repression is impossible because attention is wholly absorbed, and the inward pressure is relieved through the safety valve of vehement demonstration, but in all emotion short of this acme it is habitual and systematic restraint that should be aimed at.

"No one," said Maudsley, "can resolve successfully by a mere effort of will to think in a certain way or to feel in a certain way, or even to act always in accordance with a certain rule, but he can, by acting on the circumstances which will in turn act on him, imperceptibly modify his character; he can learn to withdraw his mind from a certain train of thought, the activity of which will thereupon subside, and can direct it to a different train of thought which will thereupon become more active."

Its Contradiction of Accepted Principles.

The fixing of attention upon some indifferent or different thought while poignant memories occupy the mind is always a difficult, sometimes an impossible, task, but it is the only way of obtaining relief, and it is the way in which our war-worn men have sought refuge from their reminiscent troubles. Attention in them, instead of moving freely from point to point with the objects presented to it, has become riveted upon some particular idea or recollection, and has become rigid. The men have tried not to think of their life in France or Belgium or Gallipoli, to occupy their minds with other interests, and to avoid newspapers and war books.

But in doing this it appears our war patients have been all wrong. They have been practising repression, which is anathema, forcing down their war memories into mysterious depths from which they emerge now and then, in curious disguises—anxiety, depression, tremors, jumpiness, dreams, dizziness, headaches, dyspepsia, and all sorts of anomalous symptoms. During the day repression can, by an effort, be maintained, but it is relaxed when night comes and the irrepressible memories bounce up in consciousness and cause insomnia or ghastly dreams. The proper course, we are assured, for men thus afflicted is to stop repression and keep their miseries ever before them. They must be persuaded to dwell on them, to describe them to their companions, to face them, and to get accustomed to them.

Now all this seems to me to be at variance with pre-war experience, at any rate, and, must I add, with common-sense. Rubbing a raw surface has not hitherto been found conducive to healing. Surely it is the experience of mankind at large that to recall our misfortunes, sorrows, and follies is the one sure way to strengthen and prolong their hold on us, and that the sooner they are ousted by neutral or pleasant memories the better for our equanimity. Would it be prudent to recommend a hypochondriac to fix his attention on his abnormal sensations, and to keep bringing them to the surface for examination? Did any of us ever see a delusion cured by encouraging the patient to give expression to it and dwell on it? Is it not best to leave it alone and give it a chance to wither and atrophy. We "nurse our wrath to keep it warm," but it cools down if we turn to something else. "With a mental grief as with a physical pain," said Maudsley, "the right course is not to foster increased action, but to give it rest, and to allow the healthy energy of neighbouring parts to encroach gradually upon, and to subdue, the morbid action."

It is, from a hygienic point of view, the supreme virtue of the confessional that it confers what the psycho-analysts would call his much deprecated repression. By creating a belief in forgiveness it abolishes qualms of conscience which might unbalance the mind. Much melancholia has been attributable to keeping within the sphere of attention memories of faults and transgressions which should have been driven away by wholesome recreation; much, too, has been due to the hugging of sorrows which should have been discarded. Believing what I do of anti-repression, I am not surprised to find that those who practise it acknowledge many failures. I am, however, surprised to note that in a number of the cases reported as successful there is no evidence that the patients had been deliberately repressing certain painful elements in their mental content. They had simply and instinctively been trying to withdraw attention from the painful content and to fix it on other mental contents of a less painful or pleasurable kind, in accordance with the common custom of mankind. Dr. Rivers narrates an interesting case illustrating this point. It is that of an officer who "had found on the field of battle the body of a fellow officer blown into pieces, with head and limbs lying separated from the trunk, and who, from that time, was haunted by the ghastly vision of what he then saw. When he slept he had terrifying nightmares of the mangled remains of his friend, and so he dreaded to go to bed, and spent each day in painful anticipation of the night, and awoke during the night pouring with sweat." The psychotherapy in this case consisted in pointing out to the patient that the mangled state of the body of his friend showed that he had been killed outright and had been spared the prolonged suffering which is too often the fate of those who sustain mortal wounds. He brightened at once, and was ultimately discharged recovered, although he seems to have suffered from at least one terrifying dream after his discharge. Now, what psychotherapy, I would ask, is there in this? Was there ever a case of sudden death in which this euthanasia specific was not administered to the sorrowing relations? Was there ever a mourner under such circumstances to whom, not being an idiot, the consolatory reflection, for whatever it is worth, did not spontaneously occur? *But what had repression, or the relief of repression*, got to do with it? It was substitution, and not anti repression, that availed There had been no forcing down of a hideous memory It was on the surface, and was merely glossed over by the reflection that the friend's death was painless But this officer, it seems before he encountered the horrid sight that is alleged to have overcome him, had been buried as the result of a shell explosion, which had been followed by symptoms pointing to some degree of cerebral concussion, and it was, I suggest, cerebral changes due to the concussion with the lowered power *of resistance they involved that enabled the horrid* sight to take such a persistent grip of him—a grip which it gradually relaxed as these changes were rectified Then, before the simple psychical anodyne of reminding him that his mutilated friend had suffered *no pain* was administered, he had been advised to keep all thoughts of war from his mind and it was perhaps compliance with this—certainly not anti repressive advice—that did him good

---

* Part I. was published in THE LANCET, June 5th, 1920 (p. 1248).

Its Application to Dreams

The anti repression policy is applicable, *we are assured*, to dreamland as well as to daily life Disquieting dreams, nightmares, and insomnia have always afflicted those who have taken part in war Sir Walter Scott noted this

> Soldier rest thy warfare o'er,
> Sleep the sleep that knows not breaking,
> Dream of battlefields no more,
> Days *of danger nights of waking*

But the appalling features of modern warfare have given to the dreams of our soldiers a peculiarly disturbing character which renders their alleviation more than ever desirable Well, that *alleviation, according to the psychoanalysts*, consists in anti repression They teach that the patient suffering from such dreams must, on going to bed, make no effort to banish the remembrance of them, but must rather recall them, lest the dream substance, buried in the subconscious, may emerge therefrom during sleep How the burial was effected is not clear, but the reason for the nocturnal resurrection is obvious enough The mind is then no longer preoccupied by opposing impressions, but is left to ruminate on its contents, and the higher controlling centres being the first to go dormant, the lower or emotional centres are *free to agitate The view that* this agitation may be prevented by its voluntary initiation, just as sleep is impending is certainly not in accord with the popular notion on the subject or with physiological principles Recurring bad dreams are common enough They grow out of the cares of peace as well as out of the pangs of war, and the accredited mode of warding them off is to occupy the subsomnolent *mind with something as remote from them* as possible The man who carries his worries to bed with him will get no sleep, or sleep with dreams in which these worries are mixed up, and of the thousand expedients that have been devised to invite sleep when it is thus coy, and to keep it clear of worrying dreams, there is not one that consists in conjuring up the worries and turning them over in the mind just when sleep is invited The *rational treatment of* insomnia is to discover the precise nature of the anxieties that are keeping the patient awake and remove them Agreed! But how is this to be done? The anxieties are often real and clamant enough, and where they are fictitious they cannot be enucleated like an encysted tumour The only way to dispose of them is to think of something else, or to circle *round them at an ever increasing distance in* thought until they are lost sight of altogether [or to blunt the sensibility of the cerebral centres by sedatives and narcotics

The Tendency to Emphasise Mental at the Expense of Physical Factors

The tendency of the psychoanalytical school appears to be to seize on and emphasise mental factors in the psychoneuroses, and to pass lightly over personal physical factors of at least equal significance *In illustration of the effects* of repression there is described the case of an able pilot in the R A F, who, when returned to duty after a crash, was ignorant of the construction of an aeroplane and denied that he had ever been in the air But surely the crash was enough to account for this state of matters, without assuming a stand up fight between fear and a sense of duty or any forced repression of a *tormenting* idea which should have been bravely confronted We find frequently ascribed to repression cases of complete amnesia in men returning from the front with a large block *of their mental life* blotted out Intense emotional stress has no doubt caused new departures in the war, but in civil practice I have never seen complete retrograde amnesia in a healthy young or middle aged man, arising out of emotional excitement or mental struggle, but I have seen it constantly as a consequence of trauma or toxæmia I would say that invariably after concussion *there is forgetfulness of the* events immediately preceding the accident, the impressions then received having been, as it were, developed but not fixed in the brain and remaining permanently irrecoverable When the amnesia exceeds this and extends back for days or weeks, then it may be safely inferred that there has been a *physical lesion* That *fear* or mental shock without physical commotion should leave complete amnesia behind it is improbable, as the rule is that objects of alarm are exceptionally impressive The whipping of boys at parish boundary lines was *intended to ingrain the remembrance* of the landmarks But the perturbation of fright in its excitement of the perceptive powers makes a more indelible stamp than even an acute bodily infliction, and it seems unlikely that fright alone should have created a big gap in memory in war neuroses men

That externally induced psychical states have played an essential part in the production of many of the war psychoneuroses is undeniable, and that the counteraction of these states by a psychical antigen self produced, or by a psychical antidote therapeutically administered, has in many cases been *eminently beneficial, cannot be gainsaid, but it remains* to be determined within what limits the psychical antidote is efficacious, and how far, when efficacious, it is assisted by concomitant physical changes The purest of the psychoneuroses are apt to set up a recurrent habit, and, if unrelieved, to run into structural changes that are beyond the reach of unaided psychical remedies

General Conclusions

In a large number of cases in which psychotherapy has been successful there have been coincident with it changes in environment, companionship, diet, and employment, which may have contributed largely to the favourable issue, and in a number of cases in which it has been unsuccessful the *lapse of time, fresh air*, exercise, games, shooting, or fishing have ultimately secured complete recovery It is quite unjustifiable to talk of the futility of voyages and rest cures and changes of scene in the psychoneuroses, which, *long before psychoanalysis*, as such, was heard of, and without any preceding psychoanalysis beyond an accurate diagnosis, have in countless cases conduced to perfect recovery When the new psychotherapy has as good a record of permanent cures as these methods of treatment it will command fuller acceptance than it does to day, and, as things stand at present, I *would not exchange for it the use of the bromides alone* The extremes to which the psychoanalysts push their panacea is illustrated by Jung's contention, in defiance of all observed facts, that the psychological factor plays a decisive *rôle in the origin* and course of dementia præcox Those of us who have watched the slow progress of the malady, sometimes from early childhood, who have noted the physical abnormalities *and signs of defective development and* degeneration which are so commonly associated with it, will not assent to that view of it

I would be the last to depreciate the importance of the psychical *factor in the causation* of insanity, *or in its treatment*, but I must again, in justice to our department, insist that psychotherapy is no new discovery Moral treatment, as it has been called, *has long been diligently carried out in* our asylums I open at random a British asylum report for the year 1857, and I find recorded under moral treatment first, occupations of many kinds—gardening, field work, *carpentry, turning*, sewing, *knitting, printing, secondly*, amusements, dances, theatricals, concerts, bowls, cricket, billiards, excursions, thirdly, instruction, lectures, and classes for modern languages, music, *and drawing*, and more than that, I find testimony borne to the restorative influence of the personal intercourse of the physician with his patients, and of the impact of the sound on the unsound mind "The *advantage*," the report says, "of the association with healthy and vigorous minds has long been recognised in the treatment of the insane Reading is no substitute Communion thus *with the thoughts of even the wisest and best* has not the influence of personal intercourse The latter is regulated according to the varying phases of the emotions, and while new images and suggestions and sympathy are poured into the wounds of the sufferer, they are adapted to his character and condition "

That the very same kind of moral treatment thus practised *in our asylums nearly three-quarters of a century ago is still* efficacious to day is evident, for Dr R T Williamson, of Manchester, as the result of his experience, recommends in psychasthenia after shell shock suitable occupations, such as netting fretwork, wood carving, sewing, knitting, basket-making field work, gardening, and motor wagon driving, games, such as draughts, dominoes, cards, and billiards, and studies, such as *foreign languages, drawing, painting photography*, and music Dr Williamson recommends also prolonged sleep, and accentuates the importance of avoiding the reading of war news, *the discussion of symptoms with* other patients, and the direction of the thoughts into new channels Sir Frederick Mott has testified to the benefit derived by soldiers suffering from shell shock at the Maudsley Hospital, *from field work, gardening, poultry keeping, metal* work, and carefully regulated physical exercises Much sound psychotherapy lurks behind the sweat of the brow.

THE CONTINUITY OF HOSPITAL TREATMENT.

AN interesting address on Old London and the Origin of the London Hospitals was delivered at St. Thomas's Hospital on May 28th by Mr. G. Q. Roberts, the secretary of the hospital, mainly with the object of drawing attention to the admirable work of the League of Mercy. Incidentally, however, the lecture was a powerful plea for the continuance of the voluntary system of hospital maintenance, which, as Sir William Collins, who presided, pointed out, has played a very important part in the social life and history of London.

The lecture was a running commentary on a large number of maps, plans, and pictures of old London and its hospitals, which were thrown upon the screen. By way of striking contrast with the quaint views which were to follow, the first picture showed St. Thomas's Hospital at the present time, taken from an aeroplane, and presented a view of the river Thames with Westminster Bridge running diagonally across the picture, the hospital being at one end and the Houses of Parliament at the other. So imposing are the buildings of the hospital, especially when viewed from the terrace of the House of Commons, that a visitor from the United States when being entertained by Members of Parliament at tea mistook the structure for the Houses of the "Principal Aristocracy," said Mr. Roberts.

Provision for the Sick in Olden Times and Now.

It is almost impossible at the present time, the lecturer continued, to realise exactly what London was like in the past, for its origin lay hidden in remote antiquity. The river afforded easy means of communication and, surrounded as the place was by marshes, one could easily understand why it should have been selected as a stronghold. After the arrival of the Danes it was strongly fortified, and the renewed Roman wall stood well on into Tudor times. After the Norman Conquest many religious houses were built, and these occupied about one-third of the city, large numbers of the inhabitants being employed in and about them. Most of these houses made provision for the sick poor, and long before the thirteenth century St. Thomas's Spittal had been established as an offspring of St. Mary Overie, while St. Bartholomew's was connected with the priory of Rahere, and St. Mary's Spittal, which gave rise to Bethlehem Hospital outside Bishopsgate, was founded about 1256.

When Henry VIII. closed all religious institutions and confiscated their properties London suffered greatly owing to lack of hospitals for the poor, and the citizens were greatly inconvenienced by the odours emanating from the sick lying about the streets. The citizens petitioned the King for the restoration of the hospitals, and before his death Henry restored St. Bartholomew's to the people. It was, however, Edward VI. who granted a charter conveying to the mayor and corporation rights by which St. Thomas's was given for the treatment of the sick, Christ's Hospital for the education of neglected and fatherless children, Bridewell for malefactors, and Bethlehem for the treatment of the insane, these being coördinated with the work of St. Bartholomew's. Bridewell and Bethlehem were joined together in one institution. The citizens of London at once set to work to organise the raising of funds, householders were individually called upon, and arrangements were made for appealing to the congregations in churches, sermons being written for and supplied to those preachers who were by themselves incapable of moving the hearts of their hearers.

After the Fire of London medicine and surgery made great advances, and the needs and requirements of the sick poor became insistent. New hospitals were established and actively supported by Cheselden and his colleague Mead, St. Thomas's and St. Bartholomew's Hospitals providing the staffs for carrying on the work. Incidentally the lecturer remarked that Cheselden was not only a great surgeon but the actual architect of old Putney Bridge. Guy's Hospital was built on a site secured from St. Thomas's, and Westminster, the London, Middlesex, and St. George's Hospitals followed, the tendency being to keep the institutions outside London.

Continuity of Treatment.

In conclusion, Mr. Roberts said that the voluntary hospitals of London were going through a very difficult time. While their income had not advanced their expenses had increased, and they had to move with the times and pay higher salaries, inadequate though they were. Many people were ready to say "let the Government take over the hospitals," but the voluntary system of London had existed through centuries, and those people who had seen something of institutions which had come under Government control and who knew the work of hospitals insisted, in the best interests of the community, that the voluntary system should be maintained. The Government would have to give some help, but in such a way that the voluntary principle was not destroyed, every encouragement being given for carrying on the advance which history showed had been made in the treatment of the sick poor, and until perfection was reached.

REFERENCE BOOKS.

THE selection of a suitable school is a question of anxiety to all parents, and in these days of high prices and attenuated incomes it becomes more than ever necessary to obtain accurate information as to the standard of teaching and the fees to be paid before a decision is made. Great help is afforded in this connexion by the "Public Schools Year Book," which appears again as a comprehensive guide to public and preparatory schools, universities, professions, public services, and business careers. Edited by Mr. H. F. W. Deane, librarian to the Dean and Canons of St. George's, Windsor, and Mr. W. A. Bulkeley Evans, secretary to the Head Masters' Conference, of which it is the official book of reference, the year book gives a list of schools in alphabetical order, together with staffs, fees, and scholarships. A tabular arrangement of medical scholarships gives the name of the scholarship, its annual value, how long tenable, and the conditions attached to it. The brief notes on openings for young men in both professional and business undertakings include pharmacy, and welfare work. —A companion volume to the above is the "Girls' School Year Book (Public Schools), 1919–1920," the official book of reference of the Association of Head Mistresses, in which similar information similarly arranged is provided for those seeking educational institutions and careers for girls. Both books are published by the Year Book Press, Limited, 31, Museum-street, W.C. 1, the price of the first-named being 10*s.* 6*d.* and of the second 7*s.* 6*d.*

The Year Book of Scientific and Learned Societies of Great Britain and Ireland, 1919, just issued, is a useful compilation, containing as it does a record of the work done in science, literature, and art during the session 1918–19. Of its 336 pages 35 are devoted to medicine, though there are, of course, many papers of interest to medical men to be found in the sections devoted to chemistry, biology, and psychology, as well as in general science. Under the various sections are given the addresses of the societies, their objects, date of meetings, subscriptions, names of officers, publications, and the names of papers read during the session, a very full index to the societies making reference easy. Twenty-six societies not previously appearing in the Year Book now find a place, and music claims its place among the learned societies. The section of medicine is naturally headed by the Ministry of Health. Messrs. Charles Griffin and Co., of Exeter-street, Strand, are the publishers.

HAND-PROPELLED TRICYCLES FOR THE TOTALLY DISABLED.

IN view of the "rally" of hand-propelled tricycles which is to take place at Regent's Park, London, to-day (Saturday), the Ministry of Pensions state that the provision of hand-propelled tricycles in cases of total disablement was not, until two years ago, a recognised duty of the State. During the late war, until April, 1918, the Lord Kitchener National Memorial Fund supplied 276 machines, but from that date the Minister of Pensions has been responsible for the supply where a machine is essential for a man's health or to enable him to get to and from his work. Thus, in all cases of amputation of both legs a hand-propelled tricycle may be provided for outdoor use (and in addition, where required, a Merlin chair for indoor use). In paraplegic cases similarly a tricycle may be provided as soon as the man is medically certified to be able to make use of it for the benefit of his health. Machines may also be supplied on a medical certificate that they are necessary, on the grounds above mentioned, to men who have suffered amputation of one leg and one arm, and in other cases of grievous disablement, each of which is dealt with on its merits. Applications are made through the Local War Pensions Committee. The total number ordered by the Ministry up to May 31st, 1920, was 1455, of which at least 1350 have been supplied. It is known that the number of men who have suffered amputation of both legs is 961, and it may be taken that about 900 of these men are in possession of machines. The remaining 550 are for paraplegic and other special cases. The Ministry are responsible for the repair and renewal of the machines, and of those provided by the Lord Kitchener Fund.

AN OPPORTUNITY FOR INVALIDS.

To the Editor of THE LANCET.

SIR,—To those cut off by bodily weakness from the wider activities of life the Invalids' Auxiliary of the Edinburgh Medical Missionary Society offers an interesting opening. The Auxiliary was founded some fifty years ago, and has as its aim to give invalids an opportunity of helping fellow sufferers in other lands. A sale is held about the end of the year in Edinburgh of work contributed by members of the Auxiliary, the proceeds being apportioned amongst various medical missions. Contributors are kept informed as to the destination of their gifts, and an endeavour is made to establish a living link of sympathy between those who give and those who get. To many invalids in past years the Auxiliary has brought an added interest in life, and a congenial means of useful service. The committee will welcome new contributors, and would suggest to doctors and nurses who have the care of invalids to bring this form of activity to the notice of their patients who would benefit by being interested in helping other sufferers.

Further particulars will gladly be furnished by Miss Clark, 16, Coates-gardens, Edinburgh, or Miss Annie Walker, assistant secretary, E.M.M.S., 56, George-square, Edinburgh.

I am, Sir, yours faithfully,

H. F. LECHMERE TAYLOR, M.D.,
Secretary and Superintendent, Edinburgh
Medical Missionary Society.

May 25th, 1920.

Hunterian Lecture

THE INFLUENCE OF NERVE IMPULSES ON VISCERAL DISORDERS.

Delivered at the Royal College of Surgeons of England on Feb. 9th, 1920,

BY H. TYRRELL GRAY, M A., M C CANTAB., F.R.C S ENG ,

SURGEON TO OUT PATIENTS, WEST LONDON HOSPITAL SURGEON TO HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, AND TO THE ITALIAN HOSPITAL HUNTERIAN PROFESSOR (LATE ARRIS AND GALE LECTURER) ROYAL COLLEGE OF SURGEONS OF ENGLAND

MR PRESIDENT AND GENTLEMEN,—The clinical study I have made of this subject arose insensibly out of an investigation into the nature of surgical shock some years ago in conjunction with Dr. Leonard Parsons I wish at the outset to repeat the apology then offered for inevitable shortcomings in so complicated a subject, involving a familiarity with such specialised subjects as physiology and comparatve anatomy, which a clinician can hardly hope to command I am also anxious to apologise for any deficiency of clinical material brought forward. The difficulty of tracing cases after some years is well recognised, and in addition the recent dislocation of national life deprived me of much material I had hoped for

If the normal mechanism by which food is passed along the intestine depends upon a complicated and coördinated series of nerve impulses or reflexes (which are as yet imperfectly understood), clinical study of the means by which the delicate adjustment of these impulses can be deranged in disease may, in the future, throw light on many unsolved problems

Such a hope forms my excuse for attempting such a difficult subject, approached from an entirely different point of view from that of the scientific investigator, and I ask the indulgence of those whose special subjects are trespassed upon Clinical evidence is usually indirect, often misleading, even so, I hope to make my deductions as impartial as possible

A *Normal Intestinal Movements*

These are of two distinct varieties—peristaltic and rhythmic—and in connexion with these there are three factors to be considered (1) involuntary muscle, with its faculty of responding to stretching by contraction and its rhythmic properties, (2) sympathetic nerve supply, the stimulation of which inhibits the contraction of intestinal muscle, except at the sphincters, where the reverse effect is obtained (as shown by Elliott in the case of the ileo cæcal sphincter), and (3) parasympathetic nerve supply, whose action is to cause contraction of intestinal muscle, consisting of the vagus for the stomach and small intestine and the pelvic visceral nerves for the large intestine Both of these end in the junctional tissue of Auerbach's plexus

The *peristaltic wave* may be regarded as the response of the intestine to the mechanical pressure stimulus of its contents, and differs from the more rapid rhythmical waves in that each contracting segment is accompanied by a synchronous inhibition of the segment immediately distal to it The contracting segment closes on the intestinal contents which following the line of least resistance are forced into the inhibited segment, when the same process is repeated This wave of contraction and inhibition travels down the intestine driving the contents with it a process assisted by increased rhythmical contractions above (Bayliss and Starling) The rhythmic waves are not accompanied by such an inhibited segment, and their obvious function is to churn up and distribute the contents over as wide an area as possible They appear to have another function, to which I will refer in a moment

The mechanism of the true peristaltic wave appears doubtful Bayliss and Starling suggest that it is dependent on a local reflex in Auerbach s plexus though this plexus appears to be connected with the termination of the vagus fibres only Such a local reflex would appear to be unique in character

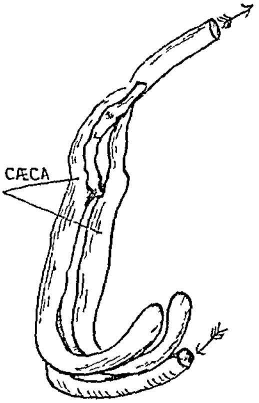
I hope to adduce clinical evidence in favour of the view that it is possible to stimulate mechanically the non medullated sympathetic fibres in their course *If this is really so, is it not possible that the contraction, elicited by the mechanical stimulus of intestinal contents, is itself responsible for exciting mechanically the intramural inhibitory sympathetic fibres to the segment immediately in front?*

Further the function of Meissner s plexus is unknown but is it not possible that this gangliated plexus is associated with these inhibitory sympathetic fibres, which receive their mechanical stimulus through its agency? Suffice it that the presence of sufficient contents in the intestine to excite a mechanical stimulus seems normally to be the exciting cause of a peristaltic wave, and perhaps to be associated with a stimulation of the intramural efferent sympathetic fibres in the segment concerned

A reference to comparative anatomy teaches us that the intestinal tract develops its modifications to suit the character of the food If we exclude the most primitive forms where the small and large intestine are in direct linear continuity (the differentiation being characterised by numerous variations from a mere increase in calibre to the development of large symmetrical pouches or cæca) for present purposes we may classify the types roughly into those found in herbivora at one extreme and carnivora at the other Thus speaking broadly, in herbivora the food is very bulky, difficult to digest and contains a minimum of nutritive elements in a maximum of bulk In such animals the cæcum with appendix is developed and highly specialised as a propelling organ to a marked degree (e g, the rabbit) It seems evident that the highest differentiation of small from large intestine evidenced by a rectangular junction of the two so cuts off the one from the other that a separate mechanism is developed for the initiation of the peristaltic waves along the large bowel Food therefore, collects in the large coiled cæcum and appendix until its bulk is sufficient to elicit by a mechanical pressure stimulus peristaltic contractions along the axis of the large intestine

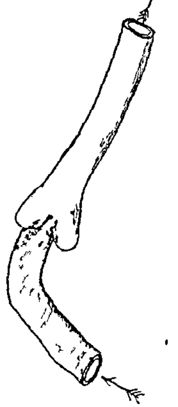
At the other extreme are those types whose food becomes more and more concentrated in a progressively decreasing bulk In these types it is clear that if distension by bulk were to be the principal factor in initiating peristalsis the food would have to collect for an unnecessarily long period before this would be effected Accordingly, the necessity for the cæcum and appendix as a propelling organ disappears as we approach these higher types culminating in man, where we find as usual the involution of the appendix characterised by its extreme variability in size and position This contrast is particularly well illustrated by a comparison of the types of cæca found among carnivorous and herbivorous birds the former having very short broad, symmetrical pouches while in the latter the symmetrical cæca are thin narrow necked and very long (Huntingdon) (See Figs 1 and 2)

FIG. 1



Cæca of herbivorous birds (the hen) (After Huntingdon)

FIG. 2



Cæca of carnivorous birds (double crested cormorant) (After Huntingdon)

The gradual involution of the appendix and shortening of the cæcum—i e, an approach to the human type—is illustrated in the case of some of the monkeys, while with the assumption of the upright position in anthropoid apes the resemblance becomes closer The more easily digestible food in these higher types is also submitted to a more rapid transit through the bowel after a more complete and rapid segmentation in the small intestine

These considerations seem to justify the view that whereas peristalsis may be the main mechanism of propulsion when food is bulky and slow in transit a more complex mechanism is essential when it is concentrated and largely fluid (at least when it reaches the intestine) Accordingly, in the highest types—i e, man—we find superimposed a more complex mechanism of rhythmic contractions associated with a specialisation of Auerbach s plexus which has in recent years been worked out by *Professor Arthur Keith and forms* the basis of his nodal theory

Rhythmic waves of contraction (an inherent property of intestinal muscle) are accentuated in the stomach and small intestine by the vagus in the large intestine by the pelvic visceral nerves—conjointly termed the parasympathetic—and both terminating in the junctional tissue of Auerbach s plexus *Professor Keith tells me that though Auerbach s plexus is plentiful in the lower animals he finds it more highly differentiated in the highest types This fact seems to me to support the view just expressed that a more complex mechanism of nerve impulses is developing as an adjuvant to the more primitive mechanism of peristalsis as the food decreases in bulk*

There is no need to refer in detail to the now well known ' nodal theory of Keith it is sufficient for the moment that the nodal points act as pacemakers in their own segments for the rhythmic contractions, which become feebler towards the end of a segment immediately before the next nodal point is reached Such points are found to correspond with the areas of normal delay in the passage of food as evidenced by X ray examinations

THE CONTINUITY OF HOSPITAL TREATMENT.

AN interesting address on Old London and the Origin of the London Hospitals was delivered at St. Thomas's Hospital on May 28th by Mr. G. Q. Roberts, the secretary of the hospital, mainly with the object of drawing attention to the admirable work of the League of Mercy. Incidentally, however, the lecture was a powerful plea for the continuance of the voluntary system of hospital maintenance, which, as Sir William Collins, who presided, pointed out, has played a very important part in the social life and history of London.

The lecture was a running commentary on a large number of maps, plans, and pictures of old London and its hospitals, which were thrown upon the screen. By way of striking contrast with the quaint views which were to follow, the first picture showed St. Thomas's Hospital at the present time, taken from an aeroplane, and presented a view of the river Thames with Westminster Bridge running diagonally across the picture, the hospital being at one end and the Houses of Parliament at the other. So imposing are the buildings of the hospital, especially when viewed from the terrace of the House of Commons, that a visitor from the United States when being entertained by Members of Parliament at tea mistook the structure for the Houses of the "Principal Aristocracy," said Mr. Roberts.

Provision for the Sick in Olden Times and Now.

It is almost impossible at the present time, the lecturer continued, to realise exactly what London was like in the past, for its origin lay hidden in remote antiquity. The river afforded easy means of communication and, surrounded as the place was by marshes, one could easily understand why it should have been selected as a stronghold. After the arrival of the Danes it was strongly fortified, and the renewed Roman wall stood well on into Tudor times. After the Norman Conquest many religious houses were built, and these occupied about one-third of the city, large numbers of the inhabitants being employed in and about them. Most of these houses made provision for the sick poor, and long before the thirteenth century St. Thomas's Spittal had been established as an offspring of St. Mary Overie, while St. Bartholomew's was connected with the priory of Rahere, and St. Mary's Spittal, which gave rise to Bethlehem Hospital outside Bishopsgate, was founded about 1256.

When Henry VIII. closed all religious institutions and confiscated their properties London suffered greatly owing to lack of hospitals for the poor, and the citizens were greatly inconvenienced by the odours emanating from the sick lying about the streets. The citizens petitioned the King for the restoration of the hospitals, and before his death Henry restored St. Bartholomew's to the people. It was, however, Edward VI. who granted a charter conveying to the mayor and corporation rights by which St. Thomas's was given for the treatment of the sick, Christ's Hospital for the education of neglected and fatherless children, Bridewell for malefactors, and Bethlehem for the treatment of the insane, these being coördinated with the work of St. Bartholomew's. Bridewell and Bethlehem were joined together in one institution. The citizens of London at once set to work to organise the raising of funds, householders were individually called upon, and arrangements were made for appealing to the congregations in churches, sermons being written for and supplied to those preachers who were by themselves incapable of moving the hearts of their hearers.

After the Fire of London medicine and surgery made great advances, and the needs and requirements of the sick poor became insistent. New hospitals were established and actively supported by Cheselden and his colleague Mead, St. Thomas's and St. Bartholomew's Hospitals providing the staffs for carrying on the work. Incidentally the lecturer remarked that Cheselden was not only a great surgeon but the actual architect of old Putney Bridge. Guy's Hospital was built on a site secured from St. Thomas's, and Westminster, the London, Middlesex, and St. George's Hospitals followed, the tendency being to keep the institutions outside London.

Continuity of Treatment.

In conclusion, Mr. Roberts said that the voluntary hospitals of London were going through a very difficult time. While their income had not advanced their expenses had increased, and they had to move with the times and pay higher salaries, inadequate though they were. Many people were ready to say "let the Government take over the hospitals," but the voluntary system of London had existed through centuries, and those people who had seen something of institutions which had come under Government control and who knew the work of hospitals insisted, in the best interests of the community, that the voluntary system should be maintained. The Government would have to give some help, but in such a way that the voluntary principle was not destroyed, every encouragement being given for carrying on the advance which history showed had been made in the treatment of the sick poor, and until perfection was reached.

REFERENCE BOOKS.

THE selection of a suitable school is a question of anxiety to all parents, and in these days of high prices and attenuated incomes it becomes more than ever necessary to obtain accurate information as to the standard of teaching and the fees to be paid before a decision is made. Great help is afforded in this connexion by the "Public Schools Year Book," which appears again as a comprehensive guide to public and preparatory schools, universities, professions, public services, and business careers. Edited by Mr. H. F. W. Deane, librarian to the Dean and Canons of St. George's, Windsor, and Mr. W. A. Bulkeley Evans, secretary to the Head Masters' Conference, of which it is the official book of reference, the year book gives a list of schools in alphabetical order, together with staffs, fees, and scholarships. A tabular arrangement of medical scholarships gives the name of the scholarship, its annual value, how long tenable, and the conditions attached to it. The brief notes on openings for young men in both professional and business undertakings include pharmacy, and welfare work. —A companion volume to the above is the "Girls' School Year Book (Public Schools), 1919–1920," the official book of reference of the Association of Head Mistresses, in which similar information similarly arranged is provided for those seeking educational institutions and careers for girls. Both books are published by the Year Book Press, Limited, 31, Museum-street, W.C. 1, the price of the first-named being 10*s.* 6*d.* and of the second 7*s.* 6*d.*

The Year Book of Scientific and Learned Societies of Great Britain and Ireland, 1919, just issued, is a useful compilation, containing as it does a record of the work done in science, literature, and art during the session 1918–19. Of its 336 pages 35 are devoted to medicine, though there are, of course, many papers of interest to medical men to be found in the sections devoted to chemistry, biology, and psychology, as well as in general science. Under the various sections are given the addresses of the societies, their objects, *date of meetings, subscriptions, names of officers,* publications, and the names of papers read during the session, a very full index to the societies making reference easy. Twenty-six societies not previously appearing in the Year Book now find a place, and music claims its place among the learned societies. The section of medicine is naturally headed by the Ministry of Health. Messrs. Charles Griffin and Co., of Exeter-street, Strand, are the publishers.

HAND-PROPELLED TRICYCLES FOR THE TOTALLY DISABLED.

IN view of the "rally" of hand-propelled tricycles which is to take place at Regent's Park, London, to-day (Saturday), the Ministry of Pensions state that the provision of hand-propelled tricycles in cases of total disablement was not, until two years ago, a recognised duty of the State. During the late war, until April, 1918, the Lord Kitchener National Memorial Fund supplied 276 machines, but from that date the Minister of Pensions has been responsible for the supply where a machine is essential for a man's health or to enable him to get to and from his work. Thus, in all cases of amputation of both legs a hand-propelled tricycle may be provided for outdoor use (and in addition, where required, a Merlin chair for indoor use). In paraplegic cases similarly a tricycle may be provided as soon as the man is medically certified to be able to make use of it for the benefit of his health. Machines may also be supplied on a medical certificate that they are necessary, on the grounds above mentioned, to men who have suffered amputation of one leg and one arm, and in other cases of grievous disablement, each of which is dealt with on its merits. Applications are made through the Local War Pensions Committee. The total number ordered by the Ministry up to May 31st, 1920, was 1455, of which at least 1350 have been supplied. It is known that the number of men who have suffered amputation of both legs is 961, and it may be taken that about 900 of these men are in possession of machines. The remaining 550 are for paraplegic and other special cases. The Ministry are responsible for the repair and renewal of the machines, and of those provided by the Lord Kitchener Fund.

AN OPPORTUNITY FOR INVALIDS.

To the Editor of THE LANCET.

SIR,—To those cut off by bodily weakness from the wider activities of life the Invalids' Auxiliary of the Edinburgh Medical Missionary Society offers an interesting opening. The Auxiliary was founded some fifty years ago, and has as its aim to give invalids an opportunity of helping fellow sufferers in other lands. A sale is held about the end of the year in Edinburgh of work contributed by members of the Auxiliary, the proceeds being apportioned amongst various medical missions. Contributors are kept informed as to the destination of their gifts, and an endeavour is made to establish a living link of sympathy between those who give and those who get. To many invalids in past years the Auxiliary has brought an added interest in life, and a congenial means of useful service. The committee will welcome new contributors, and would suggest to doctors and nurses who have the care of invalids to bring this form of activity to the notice of their patients who would benefit by being interested in helping other sufferers.

Further particulars will gladly be furnished by Miss Clark, 16, Coates-gardens, Edinburgh, or Miss Annie Walker, assistant secretary, E.M.M.S., 56, George-square, Edinburgh.

I am, Sir, yours faithfully,

H. F. LECHMERE TAYLOR, M.D.,
Secretary and Superintendent, Edinburgh
Medical Missionary Society.

May 25th, 1920.

Hunterian Lecture

THE INFLUENCE OF NERVE IMPULSES ON VISCERAL DISORDERS.

Delivered at the Royal College of Surgeons of England on Feb. 9th, 1920,

BY H. TYRRELL GRAY, M.A., M.C. CANTAB., F.R.C.S. ENG.,

SURGEON TO OUT PATIENTS, WEST LONDON HOSPITAL, SURGEON TO HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, AND TO THE ITALIAN HOSPITAL, HUNTERIAN PROFESSOR (LATE ARRIS AND GALE LECTURER), ROYAL COLLEGE OF SURGEONS OF ENGLAND

MR. PRESIDENT AND GENTLEMEN,—The clinical study I have made of this subject arose insensibly out of an investigation into the nature of surgical shock some years ago in conjunction with Dr. Leonard Parsons. I wish at the outset to repeat the apology then offered for inevitable shortcomings in so complicated a subject, involving a familiarity with such specialised subjects as physiology and comparative anatomy, which a clinician can hardly hope to command I am also anxious to apologise for any deficiency of clinical material brought forward. The difficulty of tracing cases after some years is well recognised; and in addition the recent dislocation of national life deprived me of much material I had hoped for.

If the normal mechanism by which food is passed along the intestine depends upon a complicated and coordinated series of nerve impulses or reflexes (which are as yet imperfectly understood), clinical study of the means by which the delicate adjustment of these impulses can be deranged in disease may, in the future, throw light on many unsolved problems.

Such a hope forms my excuse for attempting such a difficult subject, approached from an entirely different point of view from that of the scientific investigator; and I ask the indulgence of those whose special subjects are trespassed upon Clinical evidence is usually indirect, often misleading, even so, I hope to make my deductions as impartial as possible

A *Normal Intestinal Movements*

These are of two distinct varieties—peristaltic and rhythmic—and in connexion with these there are three factors to be considered (1) involuntary muscle, with its faculty of responding to stretching by contraction and its rhythmic properties, (2) sympathetic nerve supply, the stimulation of which inhibits the contraction of intestinal muscle, except at the sphincters, where the reverse effect is obtained (as shown by Elliott in the case of the ileo cæcal sphincter), and (3) parasympathetic nerve supply, whose action is to cause contraction of intestinal muscle, consisting of the vagus for the stomach and small intestine and the pelvic visceral nerves for the large intestine Both of these end in the junctional tissue of Auerbach's plexus

The *peristaltic wave* may be regarded as the response of the intestine to the mechanical pressure stimulus of its contents, and differs from the more rapid rhythmical waves in that each contracting segment is accompanied by a synchronous inhibition of the segment *immediately distal to it* The contracting segment closes on the intestinal contents which, following the line of least resistance are forced into the inhibited segment, when the same process is repeated This wave of contraction and inhibition travels down the intestine driving the contents with it a process assisted by increased rhythmical contractions above (Bayliss and Starling) The rhythmic waves are not accompanied by such an inhibited segment and their obvious function is to churn up and distribute the contents over as wide an area as possible They appear to have another function, to which I will refer in a moment

The mechanism of the true peristaltic wave appears doubtful Bayliss and Starling suggest that it is dependent on a local reflex in Auerbach s plexus, though this plexus appears to be connected with the termination of the vagus fibres only Such a local reflex would appear to be unique in character

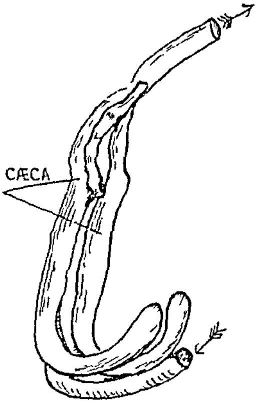
I hope to adduce clinical evidence in favour of the view that it is possible to stimulate mechanically the non medullated sympathetic fibres in their course If this is really so is *it not possible that the contraction, elicited by the mechanical stimulus of intestinal contents, is itself responsible for exciting mechanically the intramural inhibitory sympathetic fibres to the segment immediately in front?*

Further, the *function of Meissner s plexus* is unknown, but is it not possible that this gangliated plexus is associated with these inhibitory sympathetic fibres, which receive their mechanical stimulus through its *agency?* Suffice it that the presence of sufficient contents *in the intestine to excite* a mechanical stimulus seems normally to be the exciting cause of a peristaltic wave, and perhaps to be associated with a stimulation of the intramural efferent sympathetic fibres in the segment concerned

A reference to comparative anatomy teaches us that the intestinal tract develops its modifications to suit the character of the food If we exclude the most primitive forms where the small and large intestine are in direct linear continuity (the differentiation being characterised by numerous variations from a mere increase in calibre to the development of large symmetrical pouches or cæca) for present purposes we may classify the types roughly into those found in herbivora at one extreme and carnivora at the other Thus, speaking broadly, in herbivora the food is very bulky, difficult to digest, and contains a minimum of nutritive elements in a maximum of bulk In such animals the cæcum with appendix is developed and highly specialised as a propelling organ to a marked degree (e g, the rabbit) It seems evident that the highest differentiation of small from large intestine, evidenced by a rectangular junction of the two, so cuts off the one from the other that a separate mechanism is developed for the initiation of the peristaltic waves along the large bowel Food therefore, collects in the large coiled cæcum and appendix until its bulk is sufficient to elicit by a mechanical pressure stimulus peristaltic contractions along the axis of the large intestine

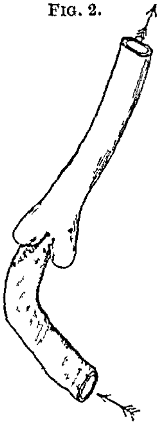
At the other extreme are those types whose food becomes more and more concentrated in a progressively decreasing bulk In these types it is clear that if distension by bulk were to be the principal factor in initiating peristalsis the food would have to collect for an unnecessarily long period before this would be effected Accordingly, the necessity for the cæcum and appendix as a propelling organ disappears as we approach these higher types, culminating in man, where we find as usual, the involution of the appendix characterised by its extreme variability in size and position This contrast is particularly well illustrated by a comparison of the types of cæca found among carnivorous and herbivorous birds, the former having very short, broad, symmetrical pouches while in the latter the symmetrical cæca are thin, narrow necked and very long (Huntingdon) (See Figs 1 and 2)

FIG. 1.



Cæca of herbivorous birds (the hen) (After Huntingdon)

FIG. 2.



Cæca of carnivorous birds (double crested cormorant) (After Huntingdon)

The *gradual involution* of the appendix and shortening of the *cæcum—i e, an approach* to the human type—is illustrated in the *case of some* of the monkeys, while with the assumption of the upright position in anthropoid apes the resemblance becomes *closer* The more *easily* digestible food in these higher types is also submitted to a more rapid transit through the bowel after a more *complete* and rapid segmentation in the small intestine

These considerations seem to justify the view that, whereas peristalsis may be the main mechanism of propulsion when food is bulky and slow in transit, a more complex mechanism is essential when it is concentrated and largely fluid (at least when it reaches the intestine) Accordingly, in the highest types—i e, man—we find superimposed a more complex mechanism of rhythmic contractions associated with a specialisation of Auerbach s plexus, which has in recent years been worked out by Professor Arthur Keith and forms the basis of his "nodal theory

Rhythmic waves of contraction (an inherent property of intestinal muscle) are accentuated in the stomach and small intestine by the vagus in the large intestine by the pelvic visceral nerves—*conjointly* termed the parasympathetic—and both terminating in the junctional tissue of Auerbach s plexus Professor Keith tells *me* that though Auerbach s plexus is plentiful in the lower animals *he finds* it more highly differentiated in the highest types This *fact* seems to me to support the view just expressed that a more complex mechanism of nerve impulses is developing as an adjuvant to the more primitive mechanism of peristalsis as the food decreases in bulk

There is no need to refer in detail to the now well known ' nodal theory of Keith, it is sufficient for the moment that the nodal points act as pacemakers in their own segments for the rhythmic contractions, which become feebler towards the end of a segment immediately before the next nodal point is reached Such points are found to correspond with the areas of normal delay in passage of food as evidenced by X ray examinations

In observing rhythmic contractions of the small intestine in the living subject, when opening the abdomen under spinal anæsthesia, I have been particularly struck with the extraordinarily small calibre maintained by the normal tone of the small intestine—a calibre which is markedly diminished by the rhythmic waves (at least, this is striking in some cases), where the diameter of the bowel appears to be reduced roughly to the size of a slate-pencil. Their function as a means of segmenting and distributing the chyme is well known; but I believe they also serve to maintain constant contractions on the intestinal contents, and when these are accumulated in sufficient bulk (i.e., particularly at the normal areas of delay towards the end of the nodal segments), to elicit that mechanical pressure stimulus which initiates peristalsis and forces the contents into the next nodal area, there to be dealt with in a similar manner.

The rhythmic waves may, perhaps, be regarded as "feelers" thrown out to ascertain the pressure, either of a bolus or collection of fluid contents; and when such a wave contracts upon contents of sufficient bulk it will, by its contraction, elicit the pressure stimulus necessary to excite a peristaltic wave which drives them onwards. These rhythmic waves, normally continuous during life, become accentuated with the physiological stimulation of the vagus, which may be regarded as the key which starts the whole complex mechanism working.

The difficulty experienced by physiologists in exciting the normal secretory and motor functions of the vagus by electrical stimulation leads one to believe that these are normally elicited reflexly by afferent impulses. Thus the sight, smell, and taste of food can initiate vagus impulses, both secretory and motor. Normally appetite is responsible, and this is usually attributed to movements of the stomach. It is difficult to see how movements of the stomach can be responsible for the sensation of appetite, since they are perhaps most marked when the stomach is full and hunger is appeased! It is, at least, not impossible that the engorgement of gastric and pancreatic glands, during the resting period, initiates an afferent vagus stimulus responsible for the sensation of hunger, and eliciting the efferent response to glands, gastric and intestinal muscle. Thus gastric movements would be coincident with, but not responsible for, the sensation of hunger. Such a view would be supported by the increase of hunger during cold weather, when surface vessels are contracted and deep structures proportionately engorged. A somewhat analogous example may perhaps be found in the afferent vagus stimulus provided by the fully oxygenated alveolus of the lung. I think there is clinical evidence in support of this view. In any event, we know that active gastro-intestinal movements and secretions are initiated by such agencies, and that this increased activity extends over the whole intestinal tract, including the large bowel, as clearly demonstrated by Hurst.

In the case of the large bowel, however, the contents being largely semi-solid or solid, the more complex rhythmic mechanism appears to be less striking, and movement of contents more dependent on peristalsis. Here the disappearance of the cæcum and appendix as an initial propelling organ is compensated by the development of a well-marked nodal point at the ileo-cæcal junction (Keith), which becomes its substitute as "pacemaker" for the ascending colon. Thus the accentuated rhythmic contractions, initiated by the vagus when food is taken into the stomach (or through the lumbar centre during defæcation), will affect the ascending colon also, and the rhythmic contractions on to semi-solid contents of large bulk will elicit strong peristaltic waves resulting in "mass movement" (the "gastro-colic reflex" of Hurst) —such a process being invigorated at each succeeding nodal segment.

The so-called "antiperistalsis," or backward movement of contents, in the colon may perhaps be explained by ordinary peristaltic contractions (evolved by the mechanical stimulus of bulky contents alone), which are too feeble to initiate a mass movement until the accentuation of the mechanical stimulus by the sudden pressure of additional food and an increase in rhythmic contractions. These feeble peristaltic contractions may be sufficient to drive the contents on a little way and allow them to slip back again, thus causing a backward and forward movement until the accentuation of the rhythmic waves initiates a mass movement onwards. Mass movement is also initiated by the act of defæcation (Hurst), the accentuated rhythmic waves being started by a reflex stimulation of the parasympathetic through the lumbar centre. It appears that, as we pass over the intestinal tract, the gradual change of the contents from fluid to solid is concomitant with a gradual decrease in the domination of the parasympathetic, a corresponding increase in the domination of the sympathetic (an essential factor in peristalsis), and also by a corresponding decrease in the rapidity of transit—in fact, a gradual approach to the predominating mechanism in herbivora. In other words, there is a varying adjustment between the opposing mechanisms of contraction and inhibition in different parts of the gastro-intestinal tract according to the character of the contents, resulting in the variation in the method and rapidity of distribution and propulsion already noted. Such a gradual reversal of the dominant innervation seems to me to be supported by a consideration of the secretory mechanisms. These are somewhat analogous in this respect: that whereas vagus stimulation is responsible for the initial secretion of gastric and probably pancreatic juice, the continuation of such secretions is mainly chemical. Langdon Brown has emphasised the fact that as we descend the alimentary canal the nervous factor in exciting secretion gradually gives way to the domination of the chemical. So that this excitation, initiated as a nervous impulse, is carried on in the stomach by gastric secretin from the pyloric glands (Edkins); in the pancreas by duodenal secretin, excited by the action of acid gastric chyme on the duodenal prosecretin (Bayliss and Starling); and in the small intestine by the pancreatic secretion and the mechanical stimulation of food (Starling).

In two such closely allied functions (secretory and motor), if the mechanism of one gradually changes to meet food requirements in its different stages, it should not be surprising to find a concomitant reversal in the other.

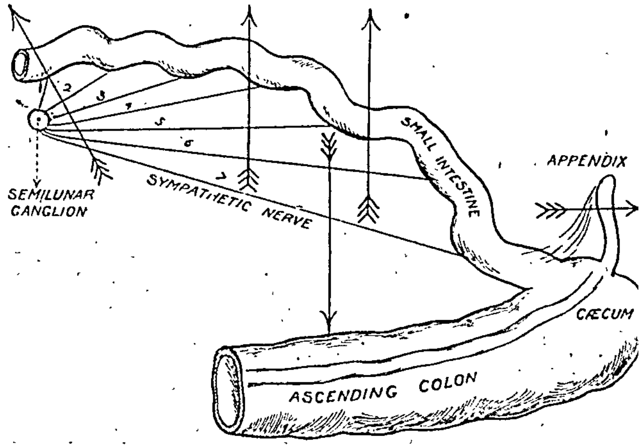
The predominance of the sympathetic or inhibitory innervation and the comparative ease with which its impulses can be excited in the lower portions of the intestinal tract play, I believe, an important part in the causation of disease.

B. *Pathological Derangement of the Normal Intestinal Mechanism.*

Lesions of the mesentery.—The difficulty of watching normal intestinal movements in man has been due to the fact that such movements cease immediately the abdomen is opened. This phenomenon has been erroneously attributed to the mere exposure of the viscera to the air. That this is not true is proved by the continuation of such movements when the abdomen is opened under spinal anæsthesia. This proves that the inhibition of intestinal movement on opening the abdomen is due to a reflex sympathetic stimulation, and it occurs even before the abdominal cavity is exposed. This is well illustrated during operations for acute obstruction. During the course of a study into the nature of surgical shock, Dr. Parsons and I made numerous blood pressure observations during abdominal operations in man and animals. We found that while local vascular effects were masked by the dominating centripetal impulses, if these were satisfactorily excluded, local changes could be well studied.

Thus, whether general or spinal anæsthesia was employed, no obvious blood-pressure variations could be attributed to manipulation or crushing the bowel wall—a fact which harmonised with its well-known "insensitiveness." On the other hand, if centripetal impulses were excluded, by operating under spinal anæsthesia, a marked rise of blood pressure arose from manipulation of, or traction on, the mesentery. Such a rise is due to a mechanical stimulation of the efferent sympathetic vaso-constrictor nerves passing through the area involved, and was proportionate to the violence of the stimulus. We found, further, that traction of the mesentery downwards induced a larger rise of blood pressure than upward traction, which indicated (Fig. 3) that the extent of the phenomenon, due to vaso-constriction, was proportionate to the number of efferent fibres mechanically stimulated. Thus, the higher up manipulations were carried out, the greater was the blood pressure excursion, until finally the greatest rise of pressure in animals was elicited by mechanical stimulation of the semilunar ganglia themselves. One fact which struck us was the domination of the sympathetic vaso-constrictor fibres in such stimuli, vagus effects being only observed during traction on the cardiac end of the stomach.

FIG. 3.



Numbered nerves stimulated by traction on mesentery in different situations. (Tyrrell Gray and Parsons.)

I was impressed at that time by the possibility that the phenomenon observed in relation to the blood-vessels might equally well apply to the intestinal muscle, possessing an analogous innervation. Accordingly, a close observation of the effect of operative manipulations under spinal anæsthesia showed that, whereas manipulations of the bowel wall alone inhibited only the tone of the section involved, manipulations of the mesentery inhibited the whole area supplied by the mesenteric nerves so stimulated. As in the case of the blood-vessels, so in the case of the bowel movements, traction downwards will inhibit a wider area than traction upwards, a larger number of nerves being involved (Fig. 3). Finally, traction and manipulation of the upper mesentery inhibits the tone of all the small intestine. We know that intestinal inhibition results from inflammatory lesions of the peritoneum, particularly the mesentery; if the possibility of mechanical stimulation to inhibition be granted, a wide field of surgical study is opened up.

Inflammatory Inhibition.

General peritonitis.—An extreme example of widespread intestinal inhibition from this cause is to be found in general peritonitis. Here the presence of pus constitutes the stimulus to the whole of the mesentery, and provides a constant irritating excitation of the efferent sympathetic inhibitory fibres to the whole intestine. The so-called "paralytic ileus" resulting is not really paralytic, but is due to continuous *active* inhibition of intestinal movement. It is to be regarded as the natural mechanism for insuring immobility and rest to an inflamed and injured structure—one of the first natural principles to be imitated in the treatment of inflammation.

Here a recognition of the nerve impulses involved guide us in the treatment of peritonitis. For, if the active efferent inhibition (persistent as long as the lesion is active) is protective in character, such an intestinal immobility is to be assisted and imitated by every means. The resulting afferent stimuli are a source of danger to the synapses of the vital centres—their mitigation is therefore indicated.

These principles largely form the basis of the Fowler treatment, which further aims at the gravitation of infective fluids to the pelvis, where the smallest number of afferent mesenteric and peritoneal nerve fibres will be stimulated To the appreciation of these factors is largely due the marked improvement in the results of the treatment of peritonitis in the last decade Nerve impulses associated with peritonitis can perhaps better be illustrated by considering a local lesion, and appendicitis may be chosen as an example

Acute appendicitis —If the comparative insensitiveness of the bowel wall, as demonstrated both by operations under local anæsthesia and by blood-pressure records be borne in mind the variability in presence, absence, or severity of symptoms accompanying the onset and progress of acute appendicitis is curious It is common experience that the symptoms often bear little relation to the lesion One feature has struck me forcibly for some years—namely, that when the appendix is extra or retro-cæcal in position the onset of vomiting and constipation is not so pronounced and is often absent This must be a common experience Indeed, it is not uncommon to find an extra or retro cæcal appendix abscess unassociated with any definite symptoms except discomfort, malaise, or a little pain, even when the local lesion is severe A perfectly free appendix, suddenly and severely infected it is true, cannot induce initial severe pain, vomiting, and constipation immediately from involvement of the adjacent peritoneum and mesentery, but it will then usually be found at operation that the mesentery is thick, œdematous, and thrombosed, and I believe that in this type the primary lesion is usually a thrombosis of the mesenteric vessels arising from acute blood infection, the appendix lesion being secondary Thus the inflamed, free, or adherent appendix stimulates its own, and the adjacent ileal, mesenteric nerves in the ileo-cæcal region, as well as those of the peritoneum, just as did general peritonitis in the case of nearly all the mesenteric nerves (The retro cæcal appendix is obviously much more limited in this respect) The result of such an inflammatory stimulus is again both efferent and afferent

The stimulus to the *efferent* nerves is evidenced by a protective inhibition of the bowel supplied by the sympathetic nerves involved—i e , the ileo-cæcal region, which would in itself delay the passage of contents, inhibit the ileo cæcal nodal point of Keith, and so lead to constipation.

The stimulus to the *afferent* ileo cæcal nerves evolves reflexly from the central nervous system a general efferent sympathetic stimulation which reacts as follows 1 Inhibition of all the intestinal muscle, particularly the large bowel which will accentuate the degree of constipation initiated by the local inhibition 2 With the inhibition of the intestinal muscle and the pyloric end of the stomach will be associated the spasm of the pyloric and ileo-cæcal sphincters 3 The stimulation of the splanchnic nerves causes an excessive secretion of suprarenal extract which still further inhibits the intestinal muscle and accentuates spasm of the pyloric and ileo cæcal sphincters Also the suprarenals being antagonistic to the pancreas the secretions of this gland will be diminished and probably to some extent intestinal secretions also *Thus pylorospasm is further accentuated* 4 That there is an associated violent afferent vagus stimulus is evidenced by the initiation of vomiting through its efferent response *Here the sympathetic stimulus does* not mask the vagus because the cardiac portion of the stomach, which is probably not inhibited by sympathetic fibres, can contract uninfluenced by such impulses This contraction of the cardiac end, when associated with sympathetic inhibition of the pyloric end and a spasm of the pyloric sphincter, explains the persistence of vomiting while the irritation of the local lesion is most active

Associated spasm of the pylorus with intestinal lesions was demonstrated by Murphy and Cannon, who pointed out that after operations on the intestine the pylorus remained closed for a variable period, depending on the situation of the trauma This reflex pylorospasm is again clearly a protective nervous mechanism to prevent the intestines functioning as long as their active inflammation calls for complete rest

How far the general sympathetic stimulus inhibits the secretory functions is doubtful That it does so through the adrenals in the case of the pancreas is probable, and in so far as secretion of succus entericus is influenced chemically by pancreatic secretion the intestinal glands may be similarly affected Clinically gastric secretion is increased

The association between the appendix and the pylorus has long been a recognised clinical fact, and the term "appendix dyspepsia" is perhaps misleading That the appendix has in itself any evident effect on the stomach I do not for a moment believe—clinical and experimental evidence is against such a view, and clinical facts adduced are too inconstant—but that the pylorus is affected reflexly in the manner shown by lesions involving the meso-appendix, the ileal mesentery, or the parietal peritoneum, from inflammation of the appendix, seems certain

I have taken the appendix as an example because of its frequency, though the same considerations naturally apply to lesions of a similar character elsewhere For example, the colicky pains caused by subacute inflammation of mesenteric glands is probably due to direct inhibition of the segment of bowel supplied by the irritated efferent sympathetic fibres I have entered in some detail into the mechanism of the nerve impulses responsible for the symptoms of acute appendicitis because it has a distinct bearing on the next aspect of my subject

Mechanical inhibition —I am now anxious to show that an analogous inhibition may result from mechanical stimulation During operations performed for the relief of acute obstruction under general anæsthesia every surgeon is familiar with the immediate protrusion of distended bowel through the incision Such patients are usually verging upon the second or depressor stage of shock, and this phenomenon is usually accompanied by a varying degree of collapse That this is not due to exposure to air or cold is shown by the fact that no such blood pressure variations are observed under ordinary conditions, nor is there the same tendency for the intestines to protrude

It might be assumed that such a sudden collapse is due to the sudden release of intra abdominal pressure That this may be a contributory factor cannot be denied, but that it is not the principal factor was shown by Dr Parsons and myself from a study of the simultaneous blood pressure, pulse and respiratory tracings in artificial distension of the bowel during sigmoidoscopy. We stated—

1 That the vaso motor variations are not due mechanically to increased pressure in the abdominal cavity For the pulse and respiratory rate are increased instead of being slowed, as would then be the case

2 That direct stimulus to the bowel wall is not responsible For our experiments have repeatedly demonstrated that manipulation of the bowel wall is without any ascertainable effects on the blood pressure

3 That distension of the intestine induces tension upon the mesentery, and from the stimulus to this structure, with its contained nerves, arises the impulse to the vaso-motor centre, to this the rise in blood pressure is responsible The stretching and stimulation of the mesenteric nerves during intestinal distension has, we believe, an important bearing on intestinal activity, blood-supply, and shock (from afferent impulses) in clinical medicine and surgery

Again, in experiments on animals the way in which distended intestines stand away from the root of the mesentery is striking There seems to be considerable evidence that distension of the intestine, beyond the normal limits at any rate, does exert a definite traction on the mesentery, and this is only to be expected on mechanical grounds if the length of its vertebral attachment is compared with that of the intestinal Such tension is naturally modified by the support of the abdominal wall, though it cannot be completely controlled when the intestines have free play for their movements I have already referred to vaso-motor and inhibitory phenomena resulting from inflammatory lesions of and experimental and operative traction on the mesentery I have also tried to show that such traction may occur from intestinal distension The results of the application of these principles in practical surgery has convinced me that there are good grounds for such an assumption, and therefore I now propose to apply these considerations to the clinical study of visceral disorders

The Development and Rôle of Mesenteric Bands.

In recent years much attention has been focussed upon various mesenteric bands found with considerable frequency in certain situations Sir W Arbuthnot Lane first described them as the crystallisation of lines of force in an attempt to support the viscera —a mechanical sequel to the assumption of the upright position An inflammatory origin has been suggested, but they are too constant in form and position to warrant this view That these develop to compensate mechanical conditions during the lifetime of an individual is most unlikely, for Professor Keith has emphasised their existence in the newborn infant, while it is not unusual to find them in varying degrees during operations on quite young children

The evolution of the large bowel in man from the types found in quadrupeds reveals its gradual *fixation* in the former as a striking feature This is as true embryologically as it is phylogenetically, and the fixation takes place by a gradual fusion of the mesentery; this is less complete in some situations than in others If we regard the present arrangement in man as transitional between that of the quadruped and the final adaptation to the upright position, we should expect to find considerable variation in the extent and method of fixation—for variation in type is one of the marked features of transition There is clinical evidence to support such a view, for almost every degree of mobility can be observed in man At the one extreme are encountered occasional instances of a perfectly free colon with a long mesentery throughout I have twice encountered this condition, and in one—a little girl of 8 years suffering from acute obstruction—a volvulus of many complete rotations was found, involving practically the whole of large and small intestine The appearances were those of nearly the whole intestine supported on a "twisted pedicle" When unravelled the arrangement approached that found in the dog

Such cases are to be regarded as extreme types of atavism At the other extreme are the well fixed colons with complete mesenteric fusion in ascending and descending colon, shortened mesentery to a high lying transverse colon, shortened and well fixed cæcum, firmly supported flexures, and a diminished loop to the pelvic colon. Between these extremes are found all transitional types in considerable variation, affecting one or every portion of the large bowel For instance, failure of mesenteric fusion and extreme mobility may affect the cæcum and ascending colon only, or together with a large loop to the pelvic colon, or both these may be associated with a pendulous and redundant transverse colon

Is it not possible that these bands represent variations in the process of mesenteric fusion and fixation in transitional types, in which occasional spurious or anomalous types of fixation may be observed? Again, the very variability in size and anatomical relationship of the appendix is an indication of its gradual involution, and I believe this to be true to some extent of the cæcum also For on several occasions I have encountered a cæcum markedly enlarged *below* the ileo-cæcal valve and hanging well into the pelvic cavity, in subjects where the mesenteric fusion was elsewhere advanced Such cases would seem to be a reversion to the type of long cæcum The most reasonable view seems to be that such bands are developmental and represent spurious efforts at fixation of the large bowel in transitional types

Situation —The commonest varieties have been described by Sir Arbuthnot Lane The most important may be enumerated—

1 Ileo-pelvic, producing the so-called Lane's kink This requires no detailed description

2 *Jackson's membrane*, which, attaching the cæcum and ascending colon to the lateral abdominal wall by a membranous sheet, sometimes develops additional thickened "constricting" bands

3 Gall bladder, pylorus, and duodenum All varieties of bands may arise from the fundus internal aspect, and neck of the gall-bladder; from the first and second parts of the duodenum, and from the pylorus These bands extend along the transverse mesocolon to its junction with the proximal and middle third of the

transverse colon; they may pass down to gain attachment to the external aspect of the ascending colon and sometimes the cæcum.

4. Membranous attachment of the cæcum and ascending colon to the proximal third of the transverse colon—this being often associated with the preceding type (3).

5. Similar attachment of the two limbs of the splenic flexure.

6. Pelvic mesocolon. The bands in this situation have been emphasised by Sir W. Arbuthnot Lane.

The first and last varieties tend, in the most advanced instances, to involve the antimesenteric border of the bowel and produce a rotation round its longitudinal axis.

There are, further, some rarer anomalies to which I should like to refer in passing.

7. Membranous adhesion of the transverse mesocolon to the anterior abdominal wall in its distal quarter or third, extending to the splenic flexure. This I have observed on three or four occasions associated with a definite prolapse. It is not likely to be seen unless looked for, owing to its remote situation.

8. Isolated round bands, the size of a stout silk ligature, are occasionally found passing from the gastro-hepatic omentum anteriorly to the stomach to the transverse mesocolon. (In one instance such a band passed from the anterior abdominal wall near the diaphragm downwards and backwards to its attachment to the anterior surface of the middle of the stomach, and was not associated with an ulcer so far as could be determined.) This was quite free, isolated, and smooth, and was associated with long-standing dyspepsia. The scar of an old duodenal ulcer was also present. In another case there were two such bands, firm, tough, and unaccompanied by any sign of local inflammation, passing across the stomach vertically from the gastro-hepatic omentum. When the transverse colon was pulled downwards both these bands markedly indented the anterior gastric wall, one over the pyloric antrum and the other about two inches to the left. Their removal, together with that of a "controlling appendix," established a cure of somewhat severe gastro-intestinal symptoms of long duration. The operation was performed a year ago. It is difficult to explain the rare existence of these bands; and it is rather tempting to attribute them to pre-natal agencies.

Gastro-intestinal Symptoms Associated with "Transitional" Bands.

Ileo-pelvic band ("Lane's kink").—Doubt has often been expressed as to its pathological significance, but its association with gastric and duodenal ulcer and with gall-stones is of too frequent occurrence to be ignored. Sir W. Arbuthnot Lane holds the view that the result of such bands is a mechanical obstruction—a view shared by many others. That this may be so occasionally in the extremest examples (when the antimesenteric border of the terminal ileum is fixed to the pelvic brim, and the gut rotated on its long axis) cannot be denied; but that such a view explains ileal stasis in the majority of cases is improbable for several reasons. For instance:—

1. The acute kinking, distortion, matting, &c., of small intestine resulting from peritonitis, trauma, &c., rarely induces any obvious delay evident under X ray examination.

2. In cases where repeated warnings have culminated in acute small intestine obstruction necessitating urgent laparotomy previous X ray examinations have proved of little help. In one such case previous X ray examination revealed no definite stasis, when acute attacks of pain of the severest character, lasting for over 20 years after hysterectomy, culminated in acute strangulation of the lower ileum for which I operated. Indeed, this is a common experience, and many instances can doubtless be quoted.

3. Even in a partial mechanical obstruction the gut proximal to the obstructed point is hypertrophied, while beyond this point it is always collapsed. Careful routine examination has never revealed any such hypertrophy above, or collapse below, the lesion; indeed, the ileum below the "kink" is usually rather "ballooned."

4. Not only is the ileo-pelvic band associated with ileal stasis, but also with delay in the cæcum and ascending colon (as demonstrated by X rays) even when the appendix is healthy. In extreme cases the bismuth may remain in considerable quantity in the cæcum and ascending colon after the rest of the intestines are entirely clear. This cannot be explained by partial mechanical obstruction.

5. Congenital inversion of the cæcum.—This condition is not infrequently encountered, the cæcum (usually of the infantile type) lying external to the ascending colon. In the extremest examples part or nearly all of the ascending colon is involved in the inversion. In such cases the terminal ileum reaches the cæcum by becoming more or less retroperitoneal and passing behind the ascending colon. I have twice encountered this condition in the extreme form and both were instructive. In one case, F., aged 35, almost the whole ascending colon was inverted, the terminal ileum being firmly embedded behind the colon in its course to the cæcum. Previous X ray examination showed marked ileal stasis. In the other, M., aged 51, repeated attacks of partial obstruction led to laparotomy. Dr. A. C. Jordan had previously demonstrated by X rays the inversion of the cæcum, which was confirmed at operation as an extreme instance, closely resembling the preceding case. In his case the ileum, proximal to its retroperitoneal passage behind the colon, showed the marked hypertrophy and dilatation associated with chronic or intermittent obstruction. But in this case no ileal stasis whatever was demonstrated by X rays.

6. Some kinking of the bowel is a normal feature at the natural points of support (i.e., duodeno-jejunal flexure, hepatic and splenic flexures), and is not necessarily associated with any pathological delay, even if acute. It is most noticeable that at such points the supporting bands or ligaments are attached to the viscus itself, never to the mesentery.

Clinical study of Lane's kink seems to show: (*a*) that "ileal stasis" is not due to mechanical obstruction; (*b*) that mechanical ileal obstruction must be all but complete before it can be demonstrated with certainty by X rays.

I have long held and acted upon the belief that the pathological effect of this band (and the "controlling appendix") was twofold.

(1) In the upright position the terminal ileum leads down to the pelvis, and the mesentery can be definitely shown to be shortened in this position. The bowel thus induces a tension on the mesentery in this situation, and mechanically irritates the efferent sympathetic nerves distributed to the ileo-cæcal region, thus inhibiting their normal rhythmic and peristaltic contractions and accentuating the normal ileal delay. (Fig. 4.) Together with this inhibition there is also a concomitant spasm of the ileo-cæcal sphincter (Elliott). Such an efferent sympathetic stimulus will further inhibit the *ileo-cæcal nodal point of Keith* and thus derange the "pace-maker" for the ascending colon; thereby causing the associated delay at this segment already referred to, by a diminution of the rhythmic waves leading to delayed excitation of peristalsis. This is analogous to the inflammatory inhibition referred to in acute appendicitis. The possible criticism that such a stimulus will equally affect the vagus fibres does not hold for three reasons: (*a*) The difficulty experienced by physiologists in stimulating the vagus in its efferent course; (*b*) the increasing domination of the sympathetic, already referred to, as we pass down the intestine; and (*c*) such sympathetic domination was shown in this region by Dr. Parsons and myself so far as it affected the vaso-motor system.

FIG. 4.

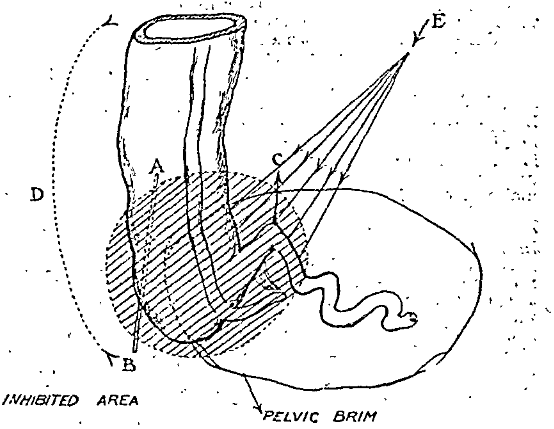


Diagram of efferent ileo-cæcal inhibition. A–B, Opening in peritoneum for cæcopexy. C, Pull on mesentery by Lane's kink. D, Area inhibited directly by secondary inhibition of ileo-cæcal nodal point. E, Lines of stress on efferent mesenteric sympathetic fibres.

(2) Such an inhibition of the ileo-cæcal angle may possibly be excited by the peristaltic wave itself. I once had the opportunity of watching an intussusception form in a loop of bowel in my hand, when operating on an infant for this condition under spinal anæsthesia. The extraordinary degree of ballooning of the inhibited segment preceding the contraction was a striking feature.

I have endeavoured to show that extreme distension will stretch the mesentery—is it not possible that, in the presence of such a "kink," on the arrival of a peristaltic wave at the area of the shortened mesentery, the widely inhibited segment may by its distension produce the drag on the sympathetic nerves that stimulates them to excite inhibition of the bowel? Even if such an inhibition is slight or partial it would tend to become progressive. Further, observations during operation have confirmed this inhibitory view. For I have noticed carefully that if the bowel be greatly drawn upon in the neighbourhood of a Lane's kink, so as to put it on the stretch, the terminal ileum becomes definitely ballooned, and the cæcum also gets distended.

If the efferent nerves are so stimulated mechanically the same effect will be observed in the afferent nerves. If it be granted that a summation of small "niggling" stimuli may in time achieve the same effect as one short violent one, the same result would be expected as in experimental or operative trauma to the lower ileal mesentery. Thus, not only should an efferent inhibition of bowel result, but also afferent stimuli exciting an efferent sympathetic response. This will result in pyloric spasm, gastric stasis, &c. (so-called "Appendix dyspepsia")—a sequel proved by X rays. Such a general, constantly repeated sympathetic reflex will not only so affect the pyloric sphincter, but will also produce a general partial intestinal inhibition; also inhibition (and so distension) of the gall-bladder, where innervation is similar to that of the intestine. The constipation, occasional pain on defæcation, and dyspeptic symptoms, associated with ileo-appendicular lesions, are fully explicable on such a view, while in their frequent association with gastric and duodenal ulcers, gall-stones, &c., such bands may at least constitute one of the many ætiological factors, primarily through constant direct and reflex intestinal inhibition.

The "controlling appendix."—I have always regarded such an appendix as one which, either by itself or through the medium of adhesions to the ileal mesentery, is capable of inducing a similar inhibitory stimulus. The mechanism of the Lane's kink and the "controlling appendix" may be thus regarded as one and the same —i.e., *inhibitory* to the normal "myenteric reflex" in the terminal ileum and the cæcum. It is clear that if the healthy human appendix still retains some of its pristine function as a "propelling organ," the controlling one not only loses such a function but actually interferes with the peristaltic and nodal mechanism of propulsion. There is thus a very simple explanation of the relief of constipation and dyspepsia in many cases where an appendix showing little disease has been removed—i.e., the release of a mutual mesenteric drag occurring during movements of the intestine.

Pelvic mesocolon.—The explanation of the pathological significance of these bands is entirely analogous to that of the ileo-colic. I have never been able to observe kinking sufficient to obstruct through their agency, and I cannot but regard their mechanism as purely inhibitory to the normal contractions of pelvic colon. Such a view will account for at least one aspect of dyschezia: for the initial act of defæcation, starting the movements of the colon, will result in tension on the pelvic mesocolon by the bands, and an inhibition of the completion of the act.

Jackson's membrane, chole duodeno-colic bands.—The mechanism of these I believe to be largely mechanical, since they are usually unattached to the mesentery proper.

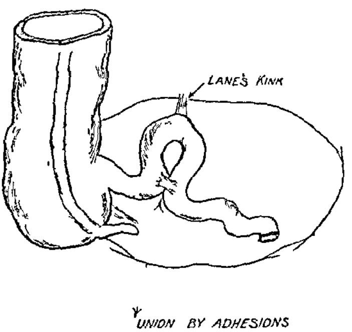
Surgical treatment.—In the treatment and after results lies such practical proof as I am able to adduce in support of these views. The simple division of such bands obviously invites a recurrence or worse. I have, therefore, for many years consistently practised free transverse division (until the bowel is quite free) with a suture of the raw surfaces longitudinally—i.e., a plastic lengthening of the mesentery of the simplest type. The numerous instances in which this has been done as a routine during the course of another operation could clearly afford little proof. I have therefore endeavoured to trace some of those cases where the routine removal of an apparently normal appendix cannot have been of influence and nothing further beyond a plastic lengthening of such bands was done. I have found 23 such cases where, so far as I could determine, there was nothing else abnormal in the abdomen. In 20 of these the terminal ileum was involved, and in 3 the pelvic mesocolon.

Ileo-pelvic cases.—The symptoms complained of were: flatulence, distension, and indigestion in 8 cases; "water brash" or "heart burn" in 2; biliousness and lassitude in 2. Pain was a prominent symptom in 10 cases; the pain was general or right-sided in 8, epigastric in 1, and in the left hypochondrium in 1. Constipation was a prominent feature in 9 cases. In one of them it is described as "markedly progressive" (this case was cured 5–6 years afterwards). It was absent in 6 cases. The results of this simple operation apply to periods of one to eight years afterwards. From 8 I have been unable to get any reply, though one of them had some flatulence three months after operation. Of the 12 cases who have replied to my inquiries, 10 describe themselves as an unqualified cure, one as a cure with occasional discomfort, one as much relieved. These figures, few as they are, represent at least 83 per cent. of cures from this simple procedure. In only one of these cases was the raw surface so large that an omental graft was used to cover it up.

In support of the benefit of this operation may be quoted one case from a different aspect—namely, that of a man aged 31, whom I operated upon for acute appendicitis in 1912. At the time of the appendicectomy a marked "Lane's kink" was noted, but was not released owing to sepsis. This patient writes me that he has no return of his acute symptoms, but suffers from indigestion, for which he has been treated.

There is one interesting anatomical feature in extreme cases—namely, that the two limbs of the tethered intestine occasionally become adherent to each other about 1½ inches from the kink, thus transforming a U into an O (Fig. 5). This condition I have encountered on at least two occasions. Even here there was no evidence of hypertrophy on the proximal or collapse on the distal side of the lesion.

FIG. 5.



Pelvic mesocolon.—The two cases which I have been able to trace 18 months and six years respectively after a plastic lengthening of the meso-sigmoid are of sufficient interest to justify a separate report of each.

(*a*) F., aged 21. A finely built well nourished, athletic girl, complaining of obstinate constipation, "indigestion, flatulence, and a feeling of great distension," for which she had received treatment. Some bands from the transverse mesocolon to the neighbourhood of the cystic duct were divided transversely and sutured longitudinally, but, though this may have influenced her flatulence, I did not think it could have exerted much influence on her constipation. There was no visceroptosis. The most marked feature was the aggravated form of the "sigmoid" bands. These were divided transversely and sutured longitudinally. An apparently normal appendix was removed. This girl is now "absolutely and entirely well" 18 months later.

(*b*) F., aged 17. This girl was sallow, thin, and unhealthy looking, and complained of obstinate constipation; the bowels were often not opened for ten days at a time. On exploration the cæcum was slightly pendulous but was not sutured. An apparently normal appendix was removed, and there was, so far as I could determine, no other abnormality in the abdomen except extraordinarily pronounced "sigmoid" bands. On dividing these transversely a large raw surface (about the size of the palm of the hand) was left, which extended well on to the lateral wall. I could not help being struck with the tension which must have been exerted by these bands, when their release left such a large gap that I could not close it by any plastic method. In this case I covered the raw surface with an omental graft. Before she was allowed up the bowels acted easily and regularly. The parents write to me she died "from other causes" last March, but that for the six years after her operation (until her death) the procedure had proved "entirely successful."

It can hardly be denied that in these cases the bands described were exerting pathological effects. Further, I am fully aware of the numerous factors entering into a surgical cure; but while bearing such possibilities in mind, I am unable to attribute the cure in the cases I have quoted to any other agency than the lengthening of the contracted mesentery. If I have succeeded in showing that their pathological effect on intestinal motor function is very rarely mechanical, it must be nervous or inhibitory in character. And again, if their harmful effects can be cured by so simple a procedure as plastic lengthening, does not this constitute indirect evidence that the mere traction exerted on the intestinal mesentery can stimulate intestinal inhibition?

Experimentally I have repeatedly tried to produce such stasis by kinking and distorting the mesentery in animals, but I never succeeded. Also it is curious that stasis associated with such bands is only to be observed from the lower ileum downwards. If the inhibitory view of stasis is accepted does not this support my conception of the increasing domination of the sympathetic, as opposed to the parasympathetic, as we pass down the intestine? Sir Arbuthnot Lane was the first to realise the predominant influence of the colon in visceral disorders, and to his genius must be attributed the stimulus to investigation in recent years. But this increased susceptibility of the terminal ileum and large intestine to mechanical nervous efferent inhibition constitutes, I believe, the main reason why these parts of the alimentary canal are so often the primary factor in the ætiology of gastro-intestinal disorders. A study of intestinal inhibition, however, is naturally not confined to its association with mesenteric bands. Having endeavoured to establish a principle I am anxious to enlarge my study by its application to visceral prolapse.

Disorders Associated with Inhibition of the Colon.

True visceroptosis, or Glenard's disease, is characterised by a prolapse of the viscera associated with a laxity of, and deficient support afforded by, the abdominal wall, including the pelvic floor. In extreme cases such a prolapse involves all the abdominal organs. The symptoms (often distressing) are familiar to all, but much of the obscurity in regard to their ætiology has arisen from the difficulty of discriminating between cause and effect, on the one hand, and from the erroneous impression that actual position in the abdomen can in itself influence intestinal function. That visceroptosis is frequently associated with profound stasis and its distressing sequelæ is common knowledge; but it is an everyday experience to find this condition pronounced in people who are in the most perfect health.

I believe the various degrees of prolapse to represent variations in a gradual transition from the type found in quadrupeds to the final position, in accommodation to the erect posture, altering food requirements, and so forth; and that the condition is in no way to be regarded as pathological. Subjects with a mobile colon, however, are definitely more liable to visceral disorders, and such anomalies should be regarded as a predisposing factor.

For a true appreciation of the pathological position of the various forms of prolapse there are two distinct factors to be realised: (*a*) Predisposing conditions; (*b*) true ætiology.

(*a*) *Predisposition* consists in the various degrees of congenital mobility and prolapse of the large bowel which invite a derangement of mechanism if a sufficiently powerful ætiological factor should supervene. In the absence of such an ætiological factor the condition is compatible, as we know, with perfect health; and I repeat there is no satisfactory evidence that prolapse of the stomach, transverse colon, or cæcum, &c., is in itself to be regarded as pathological. It is everyone's experience that this condition, even in exaggerated form, can be unaccompanied by any symptoms whatever. The most recent case under my observation is that of a girl of 25 years, perfectly healthy until after her first baby was born two years ago. Since then she has complained of pain, becoming gradually unbearable, in the right side after standing or walking for any length of time. X ray examination reveals an extreme degree of splanchnoptosis. But the point I wish to emphasise is that though there is a gastric stasis so extreme as to simulate partial obstruction (together with a marked increase of peristaltic waves over a prolonged period of at least nine hours) this patient has never had a symptom of constipation, dyspepsia, flatulence, or epigastric discomfort. Though the abdominal wall is apparently excellent and the pelvic organs are normal, it seems clear that, pronounced prolapse having been compatible with perfect health for 23 years, the ætiological factor in the onset of symptoms was the alteration of the abdominal wall and pelvic floor after childbirth.

(*b*) *Ætiological factors.*—Abdominal and pelvic support. In the case just quoted I have endeavoured to exemplify the view that visceroptosis is not per se pathological, but may become so on small provocation, which would be without influence in a subject with a well attached colon. That the abdominal wall and pelvic floor are important factors is certain. At least one of my cases on whom I performed cæcopexy some years ago remained perfectly well for a year, when symptoms gradually recurred after childbirth. This case is instructive and will be studied later. But the view that the abdominal wall can alone be responsible for the distressing train of symptoms associated with some extreme instances of prolapse cannot, I submit, be adequately supported by evidence, as I hope to show, though it certainly can initiate them. There are numbers of multiparæ, for instance, with marked visceroptosis and poor abdominal walls who have hardly a complaint; while, on the other side of the picture, we see numerous instances of unmarried girls with well-developed abdominal muscles complaining of severe and progressive symptoms.

Intestinal inhibition.—Numerous explanations have been given to account for the marked stasis often associated with prolapse. None of them are satisfactory. That the driving power of the colon is impaired is a postulate—how it is impaired is the problem. That mechanical obstruction occurs through kinking of the lumen is, I submit, quite an untenable hypothesis for many reasons:—

(1) Such a mechanical obstruction should produce hypertrophy on the proximal side. This is never seen; on the contrary, the bowel becomes very thin and ultimately inelastic. (This feature further negatives any possibility that the cause of stasis is primarily due to stretching of the intestinal muscle by bulk of contents, &c., for the normal intestine responds to increased work by hypertrophy.)

(2) The most marked kinks at hepatic and splenic flexures are often seen in those with a well-supported colon when there is no stasis at all. Some of the most acute flexures I have seen in a considerable number of personal observations under X rays, have been in people who had no stasis or constipation—and I have repeatedly verified this at operations. Recently such an extreme kinking at the splenic flexure was observed in a patient, in whom all the bismuth was evacuated within 24 hours. At a subsequent operation I found the X ray observations verified; and the two limbs of the splenic flexure were firmly united over a considerable distance, thus accentuating the kink.

(3) It is a most significant feature that, when the normal flexures of the alimentary canal are supported by ligamentous attachments, these are invariably attached to the bowel wall and never to the mesentery.

Such reasoning led me to the conviction that the normal support to the colon should be provided by attachment to the bowel itself, the object being clearly to leave the mesentery a free and mobile conductor of the vessels and nerves regulating the nutrition and movements. When the strain of support is taken by the mesentery, nerves (both efferent and afferent) are stimulated mechanically, the result being a derangement of the nervous impulses responsible for the normal intestinal contractions. If the bowel muscle is progressively prevented from contracting, then (and then only) will continuous stretching further impair its muscular action. Is it not reasonable to infer that active muscular inhibition may be the primary ætiological factor in many of these thin-walled, lax colons? The gradual domination of the sympathetic associated with an approach to the more primitive mechanism of peristalsis has been referred to in contrasting the mechanism of the colon with that of the small intestine. The ease with which sympathetic efferent effects can be evoked experimentally have also been emphasised. Once more, then, I am convinced that visceroptosis is innocuous until the strain of support is taken by the mesentery. Such increased traction initiates active inhibition, leading to overloading; while this again increases the mesenteric strain, accentuates the inhibitory impulses, and so the vicious circle is established. Thus a controlling appendix, Lane's kink, relaxation of normal abdominal support, constipation from any cause, may be the primary factor in overloading the bowel, increasing the mesenteric strain, and initiating the symptoms so often associated with visceroptosis.

In a word, the predisposing factor is visceroptosis, probably always congenital. The ætiological factor is intestinal inhibition, arising from: (*a*) deficient abdominal and pelvic support to a normal bowel; (*b*) any cause of overloading of the bowel when the abdominal wall is efficient; and (*c*) both (*a*) and (*b*) acting together. These factors start a progressive vicious circle.

The extent to which this conception is supported by the results of practical surgery forms the next part of my study, embodying a detailed analysis of 196 cases under my care during the last seven or eight years. This number represents that proportion in which I could obtain the data required for analysis. Of these 86·3 per cent. were females, and only 13·7 per cent. males. I have excluded children from this study, with the exception of three cases of unusual interest, aged 15, 10, and 8 years respectively.

Cases not Operated on.

A brief review of these is instructive for comparative purposes, and also to show that, even when not always apparent, the abdominal wall may be partly at fault. Apart from general hygienic measures palliative treatment has, in the main, been directed towards preventing overloading of the bowel, and providing adequate support of the abdominal wall by belts and corsets. Usually for the last eight or nine years I have had corsets made with the plate fixed internally, and adjusted, after the corsets are applied, by outside strap supports. This has proved the most satisfactory and comfortable, though considerable patience in repeated alterations is often necessary.

Of the 39 cases not operated on, 23·8 per cent. are cured; 57 per cent. are relieved, and in 19 per cent. treatment gave no improvement. To the failures must be added two more cases whose symptoms got worse rapidly. One has been recently operated upon, and the other awaits operation. In two cases the replies were too vague, and 16 did not reply at all.

One particularly interesting feature is the number of these patients suffering from frequency of micturition when nothing pathological in the urine was ascertained. In the whole series this symptom was present in 34·5 per cent., of whom 50 per cent. complained of frequency by day only. I have regarded it as due sometimes to congestion of a right kidney when dragged on by a mobile cæcum and ascending colon (Fig. 6); sometimes as due to the weight of a loaded transverse colon on the bladder. (I have been led to regard this symptom as possibly of importance in the prognosis of palliative treatment; for in this series six complained of it and only one was cured. Of those who ultimately came to operation this symptom was present in 23 cases, of whom a good proportion were cured.)

In 62·5 per cent. pain was a prominent feature (10 cases). Of these relief was afforded by treatment when the pain was in acute attacks or left-sided. No cases were cured who complained of dragging right-sided pain, though all were relieved to some extent by the treatment and corsets. The results from cases (50 per cent.) where constipation had been a prominent symptom did not differ appreciably from the results where constipation had not been a feature. Indigestion, flatulence, nausea, distension, &c., was complained of in 50 per cent. also; and of these 20 per cent. were cured and 66 per cent. relieved.

Though these figures are of limited value from the small number of cases traced, yet they support my previous impressions. For the small proportion cured and large proportion improved illustrates the fact that the abdominal wall, though an important factor, only plays an accessory part in the later cycle of events.

FIG. 6.

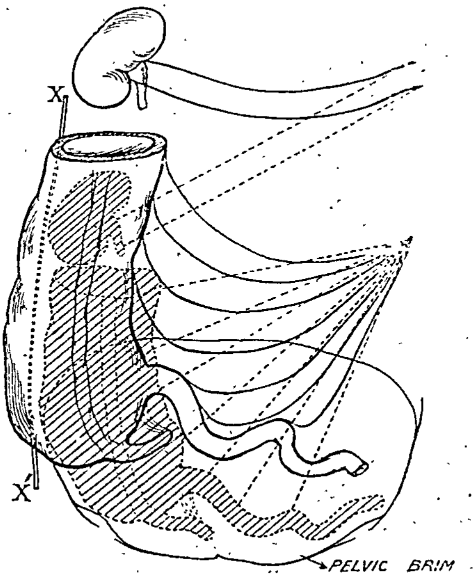


Diagram of efferent sympathetic inhibition to illustrate prolapse of the cæcum and ascending colon and resulting tension on nerve fibres. Continuous line, normal position with no tension on efferent nerves. Dotted line, prolapse associated with strain on mesenteric efferent sympathetic nerve fibres.

The other feature of interest is that the wearying dragging pain in the right side (so often erroneously attributed to mobile kidney, but really due primarily to a mobile cæcum and ascending colon) was not cured in any case, though it was improved in all. Not included in this series there is also a case in which nephropexy was performed at another hospital for this symptom with no relief. Complete cure was effected by the corsets, which are, however, indispensable. In another instance I performed nephropexy for acute renal crises with commencing intermittent hydronephrosis. This patient was completely cured of the acute renal symptoms, but for 18 months complained of a wearying dragging right-sided pain, for which I had to perform a colopexy.

A study of my cases shows that nephropexy is only justified as a measure directed against torsion of the renal pedicle (or excessive mobility,—which may make this possible), and never for descent of the kidney associated with right-sided dragging pain alone. In the latter class, if proper corsets fail to give relief, operation should be directed towards fixing a mobile cæcum and ascending colon, which is primarily responsible for the mobility of the kidney.

Finally, even if failure of the abdominal wall and pelvic floor only plays a limited part in starting a drag which leads to local or general intestinal inhibition, it is evident that if such a failure is corrected by corsets early, and the resulting inhibition eliminated before secondary factors are established, a definite cure may be achieved. This is shown by 23·8 per cent. of cures in cases not operated on; and further, by the cure of 18·7 per cent. in those who gave a history of constipation as a prominent symptom. At the same time most of the cases not operated on were of an earlier and milder type than those now to be considered.

(*To be concluded.*)

DONATIONS AND BEQUESTS.—By the will of the late Mr. Charles Adolph Heimann, of Sussex Gardens, Bayswater, W., the testator left £2000 to the University College Hospital, to endow two beds in memory of his late wife, Florence Emily Heimann; £1000 to the University College School, for general purposes; and £1000 each to the Hospital for Sick Children, Great Ormond-street, the Paddington Green Children's Hospital, St. Mary's Hospital, Paddington, to endow beds; Queen Charlotte's Lying-in Hospital, for general purposes; and Lord Mayor Treloar's Cripples' Home. He left also £500 to the Italian Hospital, London.

SOME OBSERVATIONS ON
THE INVESTIGATION AND TREATMENT OF NEPHRITIS

BY H. MACLEAN, M.D. ABERD., D.SC. LOND.,
CHEMICAL PATHOLOGIST, ST. THOMAS'S HOSPITAL; HONORARY CONSULTING PHYSICIAN, MINISTRY OF PENSIONS
AND
A. E. RUSSELL, M.D., B.S. LOND.,
PHYSICIAN TO ST. THOMAS'S HOSPITAL

WITHIN recent years various tests for the examination of patients suffering from kidney disease have been suggested, but in many cases the interpretation of these tests is still unsatisfactory, and it is quite certain that many of them are of little or no practical value. In considering the importance to be attached to any test, it is essential to have a clear understanding as to the particular defect of renal function present in the different forms of renal disease. In chronic nephritis there are two distinct conditions which stand out clearly and are exceedingly well defined by chemical investigation.

The Functions of the Kidney.

Normally, the kidney performs certain specific functions, which may be summarised as follows: (1) Removal of waste nitrogenous constituents of metabolism, such as urea, uric acid, creatinin, &c.; (2) removal of acid products from the body; (3) maintenance of the necessary concentration of salts in the fluids and tissues.

In chronic interstitial nephritis there is in severe cases a definite retention of nitrogenous waste products in the blood, and this condition is associated with a diminution in the acid excreting function of the kidney. In parenchymatous nephritis, on the other hand, there is no evidence of any retention of nitrogenous products or of failure to eliminate acid bodies, but there is often a definite failure to excrete the normal amount of salt.

In severe cases of acute disease all these phenomena may be present together, indicating a general interference with all the renal functions, but as convalescence progresses it often happens that there is a definite retention of nitrogenous waste products in some cases, while in others there is evidence of difficulty in the elimination of salt.

Defective excretion of nitrogen naturally causes an increased concentration of such bodies as urea and uric acid in the blood. Within comparatively wide limits it would appear that marked differences in the amount of these bodies in the blood does not interfere to any appreciable extent with ordinary cellular activity. On the other hand, it is most important to remember that any appreciable change in the concentration of sodium chloride in the blood is incompatible with life. It might therefore appear that any condition in which the kidneys failed to excrete sodium chloride would be one of the most serious of renal lesions, since it might tend to give rise to a fatal concentration of sodium chloride in the body. Normally, blood plasma and other body fluids contain, roughly, about 0·6 per cent. sodium chloride, and only slight variations from this figure are encountered even in patients who excrete practically no salt in the urine. When sodium chloride is retained it must be present in the body in definite concentration, and to accomplish this the body retains the necessary amount of water to yield this concentration. If much salt is retained a correspondingly large amount of water must be retained, with the result that œdema is produced. Generally speaking, each 0·6 g. sodium chloride retained requires 100 c.cm. of water. It is obvious that the same result will be produced whether the primary defect in the kidney is the elimination of salt or of water. If water is not eliminated its retention in the body tends to lower the salt concentration, and this is prevented by the retention of the necessary amount of salt to give the optimum concentration for the tissues. Salt can only be retained in the body when water is also retained and vice versa.

In parenchymatous nephritis the chief difficulty appears to be the excretion of the necessary amount of salt or of water. This results in the production of œdema, which is the most characteristic feature of the parenchymatous variety of renal disease. Strangely enough, the kidneys of such patients appear to be quite efficient in other directions, and so differ entirely from the kidneys of interstitial disease. Parenchymatous disease with marked œdema is always associated with the presence of a very large amount of protein in the urine, and consequently marked albuminuria and œdema are two of the most important symptoms in such cases.

In interstitial nephritis the picture is quite different. Here there is defective elimination of waste nitrogenous products and acid bodies, but no difficulty in dealing with salt. Hence, in typical cases, there is little or no tendency to œdema. The cardio-vascular system is involved. The urine often contains but a small amount of protein, and sometimes, even in bad cases, no protein at all can be found by the most delicate tests. Sometimes the symptoms of both parenchymatous and interstitial disease are present in the same patient, but more often very definite findings of one or other variety of the disease may be obtained.

While from clinical examination alone it may occasionally be difficult or impossible to differentiate these varieties, it is always possible to do so by chemical examination. A clear conception of the points involved is absolutely essential, for on this differentiation must be based any intelligent treatment of chronic nephritis.

The Difference between Interstitial and Parenchymatous Nephritis.

The chief points of difference between these two forms of renal disease are as follows:—

Interstitial Nephritis	*Parenchymatous Nephritis*
(1) Œdema absent	Œdema present
(2) Protein present in urine, but often slight or moderate in amount	Protein present often in very large amount
(3) Chlorides present in normal amount	Chlorides diminished or may be absent
(4) Urea concentration (urinary) decreased	Urea concentration normal
(5) Tendency to increase of urea and other nitrogenous products in the blood	No retention of nitrogenous products in the blood
(6) Cardio-vascular changes marked	Cardio-vascular changes less marked
(7) Tendency to uræmia	Uræmia less frequent

Parenchymatous nephritis.—In cases of uncomplicated parenchymatous disease, as already mentioned, the chief defect apparent on chemical examination is a difficulty in excreting salt. In certain cases sodium chloride may be entirely absent from the urine, while in others only traces may be present. It is by no means a simple process to ascertain the salt-excreting power of the kidneys, for the usual plan of giving 10 g. or more of sodium chloride by mouth and estimating the amount of this excreted in the urine is open to grave objections. Even in the normal individual a considerable amount of salt may be retained in the tissues, and it is only after repeated doses of salt given for several days that equilibrium is established and the kidneys excrete per day an amount equivalent to that taken in. In patients who are defective in the power of eliminating salt equilibrium is not established, with the result that marked and increasing œdema is produced. Even in hospital patients in the wards testing of the kidneys for salt excretion is a difficult and laborious process, while in patients seen only for a short time it is quite impossible. Practically, however, such tests are not required, for in patients in whom salt is retained to any appreciable extent the condition is obvious because of the resulting œdema. If no œdema is present it may be taken for granted that salt is not retained. In uncomplicated cases of parenchymatous disease the majority of the other tests used for estimation of kidney function give little or no information, since the results obtained are generally normal.

Interstitial nephritis.—The majority of cases of kidney disease belong not to the parenchymatous but to the interstitial type. Here careful investigation of kidney function is necessary, and most useful information is obtained by judicious examination. It may here be pointed out that the gravity of the case is in no way necessarily related to the amount of protein present, as is well known very severe cases may on some occasions show no albuminuria whatever, even when tested by the most delicate methods. Again, it has now been thoroughly established that albuminuria per se is not necessarily an indication of renal disease and may be present in individuals whose kidney function is apparently quite normal. In healthy soldiers who had just completed their training MacLean[1] found albumin in the morning urine in about 6 per cent. None of these men appeared to be suffering from defective kidney function. Further, it is possible for epithelial and hyaline casts to be present without any material or even appreciable kidney defect, so that in the absence of other symptoms the presence of albuminuria and even of casts, is not necessarily of much value in assessing the degree of renal inefficiency involved. No doubt in a general way, well marked albuminuria associated with large numbers of casts often indicates that the lesion is more or less considerable, but it is quite certain that in some cases this is not so. On the other hand, the presence of a mere trace of albumin, with few or many casts, may be associated with a very gross lesion. In spite of these qualifications the urine must in all cases be carefully examined for protein and casts.

Tests for Protein and Casts and Functional Tests.

By far the best and simplest test for protein is salicyl-sulphonic acid.

A suitable solution consists of 25 g. of the acid in 100 c.cm. water. A stronger solution may be used if desired. In testing a few drops of the solution are added to about ½ inch of urine in a test-tube. In the presence of much protein a dense white precipitate is obtained; if a small amount only is present a definite milkiness is produced, while in the presence of traces of protein a faint opalescence is obtained. The test is exceedingly delicate, and a urine in which no reaction takes place may be assumed with certainty to be protein free.

Casts should be looked for after centrifuging the urine. The only point to emphasise is the necessity for using as small a diaphragm as possible, for if this is neglected certain fine casts may be easily missed. The most suitable lens is an ordinary ⅔ objective with No. 3 or No. 4 eye-piece. A mechanical stage is useful if large numbers of specimens are to be examined.

After examining the urine for protein and casts, various tests may be employed for ascertaining the degree of involvement of the renal tissue. From an extensive experience of these tests we are of the opinion that the most useful for clinical purposes are the following: (1) Estimation of urea in the blood; (2) new "urea concentration test" (MacLean and de Wesselow[2]); (3) diastatic activity of urine.

Importance of Blood Urea.

The amount of urea in the blood of healthy individuals varies from about 15 to 40 mg. per 100 c.cm. An average figure in hospital patients with normal kidneys is, in our experience, from 20 to 30 mg. Anything over 40 may be taken as abnormally high.

When the kidney is unable to perform its normal work of excreting urea there is naturally an increase of urea in the blood. It is important to observe that even in very severe cases of nephritis the amount of urea excreted per day in the urine is the same as that of a normal individual on a similar diet, the difference between the two cases being that the patient with interstitial nephritis requires a much higher concentration of urea in the blood in order to accomplish this. If we look on the blood urea as a kind of pressure head we find that the healthy individual excretes his 25 or 30 g. of urea per diem with a head of, say, 25 mg. urea per 100 c.cm. blood, while the nephritic is only able to do this with a much larger head of blood urea; in bad cases this blood urea may be 200 to 300 mg. per 100 c.cm. blood, or even more. Thus, the concentration of blood urea is an excellent indication of the efficiency of the kidneys, for the worse the renal lesion the higher will be the blood urea. The kidneys comprise such a large mass of functionally active material that only from one-fourth to one-sixth of this is really necessary to carry out the body needs. It is, therefore, only in cases in which the kidney efficiency is reduced to one-fourth or less of its original value that there is any tendency for excess of urea to be retained in the blood. When this happens other substances, such as uric acid and creatinin, are also retained and accumulate in the blood. All these nitrogenous substances taken collectively are often referred to as constituting the "non-protein nitrogen" moiety of the blood. The amount of non-protein nitrogen present may, of course, be ascertained, and this is sometimes done in estimating kidney efficiency, but it is much easier to estimate the urea constituent alone. Since the urea concentration runs parallel in a general way with that of the other nitrogenous substances, this estimation gives all the information necessary.

From the above it will be seen that estimation of urea in the blood gives most valuable information, for when this ingredient is appreciably increased it is certain that the effective kidney tissue remaining is equivalent to less than one-fourth of the total kidney substance. In the great majority of cases of interstitial nephritis there is by no means such a marked involvement of kidney function, and therefore no evidence of increased blood urea. In bad acute cases estimation of blood urea gives invaluable information as to the course of the disease, for a progressive lesion is accompanied by a steadily increasing urea concentration, while a decreasing concentration indicates a good prognosis. In such cases it is advisable to examine the blood for urea at short intervals, for the blood urea constitutes a much safer guide than do the clinical symptoms; in fact, the latter may be quite deceptive, the condition of the patient appearing to be satisfactory in cases that terminate fatally within a week or ten days.

Estimation of Blood Urea.

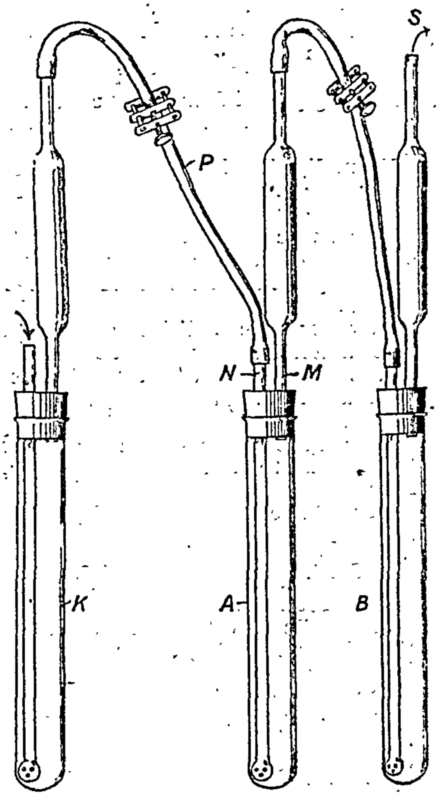
The estimation of the blood urea is carried out on the lines suggested by Marshall,[3] Van Slyke,[4] and many others. The modifications here described were suggested by MacLean and de Wesselow,[2] and have been found to work well.

The principle of the method depends on the fact that soya bean contains a specific enzyme (urease) which converts urea quantitatively into ammonium carbonate, but has no effect whatever on any other nitrogenous constituent. In the presence of alkali the ammonia is liberated from the ammonium carbonate, and by the help of a current of air is passed through a standard solution of acid. The amount of acid neutralised indicates the amount of ammonia present, and from this the urea can be calculated. Various preparations of urease, more or less pure, are now on the market, but they all suffer from the disadvantage that they are unstable, and therefore soon become unreliable. For clinical work it is far better to use finely ground soya bean meal; this can be prepared by passing the beans through a coffee machine, and it keeps indefinitely. For each experiment 0·3 g. of this meal is used, and since it contains traces of ammonia a small allowance has to be made. In various specimens 0·3 g. of the meal neutralised almost exactly 0·4 c.cm. N/100 sulphuric acid. This has to be subtracted from the total amount of acid neutralised in the actual experiment.

The estimation is carried out by means of tubes (K), fitted as shown in Fig. 1.

These tubes should be about 200 mm. deep and about 25 mm. wide. Each tube has a well-fitting rubber cork. Through this cork two small tubes pass. One of these (N, Fig. 1) has a small dilatation at the end, which is perforated with several small holes. This tube goes to the bottom of the larger tube (A). Through the other hole passes a tube (M) with a dilatation, which acts as a trap to prevent any fluid passing over. Two such large tubes are required for each estimation. To each of the small tubes passing through the rubber stopper is attached about 1 foot of ordinary stethoscope rubber tubing (P). For the accurate measurement of the blood it is best to have a special pipette made "to contain" 3 c.cm.

FIG. 1.—*Tubes for Estimation of Blood Urea.*



K, Contains 10 per cent. H_2SO_4. A, Contains blood. B, Contains 25 c.cm. N/100 acid. S, Leads to suction pump.

The materials required to carry out the estimation are as follows:—

(1) A solution containing 6 g. potassium hydrogen phosphate in 1000 c.cm. water. (2) Soya bean meal. (3) Caprylic alcohol (to prevent frothing). (4) N/100 H_2SO_4 and N/100 NaOH. (5) A saturated solution of methyl red in 50 per cent. alcohol (indicator). (6) Solid anhydrous potassium carbonate. (7) Saturated solution of potassium carbonate. (8) 2 × 25 c.cm. burettes accurately graduated in 1/10ths. (9) A pipette made to contain 3 c.cm. blood (made by Hawksley and Son, Oxford-street, W.). (10) A good water suction pump.

Method of obtaining blood.—About 10 c.cm. or less of blood are withdrawn from a vein at the bend of the elbow into a test-tube, coagulation being prevented by the use of a small amount of finely powdered potassium oxalate. The tube into which the blood is drawn must be inverted a few times to mix the solid oxalate thoroughly with the blood, otherwise coagulation may take place.

Details of Actual Estimation of Urea.

Two tubes, fitted as above described (see Fig. 1), are taken and adjusted so that the perforated inner tube (N) with the small bulb passes to the bottom of the outer tube. One of these tubes is used for the blood, while the other serves to contain the acid required for estimating the ammonia. The rubber corks and attachments are then removed and 5 c.cm. of acid sodium phosphate solution measured into the urea tube. By means of the special pipette 3 c.cm. of blood are added to the phosphate, the pipette being thoroughly washed out two or three times with the phosphate mixture so as to remove all traces of blood From 6 to 8 drops of caprylic alcohol are then added and finally 0 3 g soya bean meal The rubber stopper is now quickly replaced and the tube closed by means of clips on the rubber tubing The tube is placed in a bath at a temperature of 40 to 45° C and left there for 15 to 20 minutes During this time it should be occasionally shaken While the urease is acting on the blood urea 25 c cm of N/100 acid are added to the other tube (B) together with 1 drop of caprylic alcohol and 2 drops of methyl red solution

When hydrolysis of the urea is complete the tube is removed from the bath and connected with the tube containing the acid, so that air passing in through tube (N) will first pass through the blood and then through tube (M) to the acid in the large tube (B) To get rid of possible traces of ammonia in the atmosphere it is necessary to pass the air through a 10 per cent solution of sulphuric acid contained in tube (K) When the tubes are connected air is drawn through by means of the pump for two minutes or so By this means any ammonia present in the air in the blood tube is passed into the acid The blood tube is now opened and 4 c cm of saturated potassium carbonate solution followed by 3 g of solid anhydrous potassium carbonate added The stopper is quickly replaced and a current of air drawn through this should be slow at first but after a few minutes the pump may be turned on to its fullest capacity The time required for complete removal of the ammonia depends on the pump employed but with an ordinary pump the experiment should be complete in 30 minutes

The tube containing the standard acid is now disconnected and the acid transferred quantitatively to a small Erlenmeyer flask To do this the tube and perforated bulb must be washed two or three times with small quantities of distilled water The acid is then titrated with N/100 sodium hydroxide until the indicator gives a faint yellow colour The difference between the 25 c cm acid originally taken and the number of cubic centimetres of alkali used gives the number of cubic centimetres neutralised by the ammonia From this 0 4 c cm must be subtracted to allow for traces of ammonia generated from the soya bean

The calculation is very simple for when the above quantities are used each cubic centimetre of acid neutralised equals 10 mg urea

Estimation of Renal Efficiency in Cases showing no Increase in Blood Urea

From what has already been said it is obvious that estimation of blood urea gives information only in advanced cases of renal disease Even though fairly extensive degeneration of the kidneys may be present, it may not be sufficiently advanced to cause any increase in blood urea and this is the type of case most frequently met with in general practice Such are the cases in which it is perhaps most difficult to arrive at a satisfactory conclusion as to the real condition of the kidneys, and of all the tests used in this connexion we have found the new urea concentration test the most helpful This test in conjunction with the diastatic reaction gives most useful information

Urea concentration test—This test was introduced by MacLean and de Wesselow[2,5] about two years ago and has now been used in nearly 3000 cases It has none of the technical difficulties of the great majority of renal functional tests does not require the patient to be under observation for more than a very short time and can be carried out with the simplest apparatus The test depends on the fact that patients with defective kidneys are incapable of passing urine with a high concentration of urea even after a large dose of urea has been taken by mouth Further the degree of concentration of urea appears to be in direct relationship to the involvement of the kidneys In a normal person the urine passed one or two hours after a dose of 15 g urea should contain from 2 to 4 per cent urea In patients suffering from nephritis the urea percentage is often much less depending on the gravity of the condition If the urea percentage is below 2 the condition is unsatisfactory and the lower the percentage the more serious the lesion Cases with a concentration of urea lower than 1 per cent are comparatively rare but many moderately severe cases are unable to concentrate to more than about 1 4 to 1 5 per cent urea

Details of test—(1) The patient empties his bladder and immediately afterwards takes by mouth 15 g urea dissolved in 100 c cm of water The solution may be flavoured with a few drops of tincture of orange (2) One hour after taking urea he passes water This sample is kept and measured The urea percentage may be estimated in this specimen but as a general rule it is best to do this in the next specimen (3) Two hours after taking urea he again passes water This sample is measured and kept for urea estimation

The reason why the urea is calculated in the specimen passed two hours after taking the urea depends on the fact that urea may give rise to a certain amount of diuresis in patients who have been imbibing large amounts of fluid immediately before taking the dose This diuresis generally passes over in the first hour so that in general the specimen passed after two hours is always used for estimation of urea

Very occasionally it happens that a large amount of urine is passed during both the first and second hours in such cases a specimen passed after three hours should be examined If it is not convenient to detain the patient for three hours it may be taken for granted if no other signs of renal disease are present that the passage of very large amounts of urine giving a comparatively low urea concentration is dependent on diuresis and does not indicate kidney disease Not more than an average of 150 c cm urine should be passed per hour and in cases where 350 to 600 c cm or more are passed in the two hours of the test any tendency to a low urea concentration may be put down to the passage of excessive fluid In practice there is seldom any difficulty on this account but occasionally and especially when dealing with out patients in whom the intake of fluid cannot be regulated it is important to bear this possibility in mind So far the test has given excellent results, and in our opinion more useful information is to be obtained by this simple method than by any other functional test at present in use

Estimation of Urea

Urea is estimated by the ordinary hypobromite method

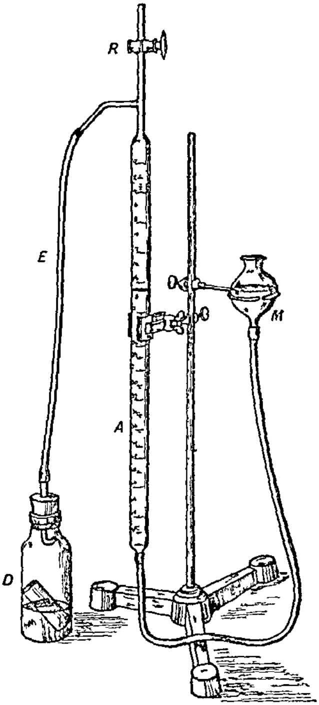
The apparatus used should give the volume of gas evolved A very suitable arrangement which is really a modification of Gerrard s apparatus is sketched here (Fig 2) This consists of an ordinary 50 c cm graduated burette (A) which has a glass tap (R) fixed at its upper end This burette is connected by rubber tubing (E) with a bottle (D) containing the urine and hypobromite solution This solution consists of about 23 c cm of 40 per cent sodium hydroxide solution to which 2 c cm of bromine are added The lower end of the burette is attached by rubber tubing to a small bell shaped vessel (M) to hold the water displaced by the evolved nitrogen

Before carrying out an experiment water is poured into the bulb (M) until it is about three-quarters full Care must be taken that no air bubbles remain in the rubber tube The water of course rises in the burette until it is at the same level as the water in the bulb

In estimating the percentage of urea 4 c cm of urine are measured into the small tube About 25 c cm of sodium hypobromite are put into bottle (D) and the test tube containing the urine placed inside the bottle so that the fluids do not mix Tap (R) is then opened and the rubber stopper placed tightly in bottle (D) Bulb (M) is then raised until the level of the water in the burette is at zero The level in the bulb will be naturally at the same level as that in the burette Keeping the level at zero the tap (R) is closed and the bulb replaced in its support The contents of the test-tube are now thoroughly mixed with the hypobromite the bottle being shaken for half a minute or so After another half minute the bulb (M) is moved so as to have the level of fluid in the burette adjusted to that in the bulb The number of cubic centimetres of gas is then read off and the urea percentage calculated on the basis of 8 c cm of nitrogen to 0 5 per cent of urea This equivalent has been worked out by estimating the average amount of urea obtained from various specimens of urine by the soya bean method and comparing these with the results obtained by hypobromite

FIG 2—*Apparatus for Urea Estimation*

(Modification of Gerrard s apparatus)



In conjunction with the urea concentration test we generally employ the diastatic test In general, when the urea test gives a low result, the amount of diastase in the urine is found to be low

Diastatic Test

This test depends on the presence of diastase (the ferment which changes starch into sugar) in the urine This diastase is obtained from the blood, which in turn gets it from the pancreas Normally, blood contains a definite amount of diastase, and when the kidneys are efficient a constant amount of this (6 to 30 units) is excreted daily in the urine In defective kidneys the amount is lower, depending on the degree of deficient renal action The diastatic activity of any specimen of urine is estimated in terms of the amount of starch which a definite volume of the urine will change in a given time, the disappearance of the starch being indicated by the failure of the mixture of starch and urine to give a blue colour with iodine. This test gives very good results when it is possible to get a sample of the 24 hours' urine, but is not nearly so accurate with single specimens of urine passed at different times of the day. A high diastatic value is in nearly every case an indication of efficient renal action.

Solutions Required and Method of Carrying Out Test.

For the test the following solutions are required: (1) A 0·1 per cent. solution "soluble" starch prepared by heating 0·1 g. soluble starch in a small amount of boiling water, cooling, and making up the total volume to 100 c.cm.; (2) 0·9 per cent. sodium chloride solution; (3) a solution of iodine about 1/10th normal.

In carrying out the test five test-tubes are taken and numbered from 1 to 5. The following amounts of urine and normal saline are then added to each tube, normal saline being used to make the total volume up to 1 c.cm. For adding the fluids 1 c.cm. pipettes graduated in 1/100ths are most suitable.

Tube No.	Urine c.cm.	Normal saline c.cm.	Tube No.	Urine c.cm.	Normal saline c.cm.
1	1·0	—	4	0·2	0·8
2	0·6	0·4	5	0·1	0·9
3	0·3	0·7			

When the tubes are ready 2 c.cm. starch solution are added to each. The mixture is then quickly shaken and the tubes put into an incubator or hot-water bath *at 37° C. for exactly 30 minutes.* The tubes are then removed and filled to within an inch of the top with cold water. This stops the ferment action. One drop of iodine is now added to each tube, beginning at No. 5. On shaking it will often be found that the last two tubes are still blue, but that No. 3 is colourless, or has only a faintly pink tint. If so, No. 3 tube contained just sufficient urine to change the 2 c.cm. of starch in half an hour. The empirical unit denoting the change is obtained by dividing 2 (the amount of starch in cubic centimetres taken) by the amount of urine in tube No. 3—i.e., $\frac{2}{0·3} = 6·6$. In the case of tubes containing fairly large amounts of urine it may be necessary to add more than one drop of iodine, since urine itself may take up some iodine. On this account the first drop of iodine may show no blue colour even when unchanged starch is present. On the addition of another drop, however, the blue colour will appear. Naturally, a greater number of tubes may be employed, but for practical purposes five are sufficient.

Other Tests.

Of the various other tests which have been recommended from time to time, perhaps the most widely used is phenolsulphonephthalein. No doubt this is a useful test, but to carry it out a colorimeter is required, and the matching of the colours is by no means easy. Sometimes attempts have been made to dispense with a colorimeter, but the error in direct estimations of the coloured solutions is so great as to render the method quite unsatisfactory. Again, the formula, suggested by Ambard and known as Ambard's coefficient, appears to be of little value except in cases where there is an increase in the blood urea; *it appears to* give no information beyond that which is obtained by estimation of blood urea. For general routine testing of kidney function we find the above combination of tests very suitable and capable of giving all the information we can hope to obtain in the present state of our knowledge of kidney function. Some results obtained from actual cases are given here.

General Clinical Examination of the Patient.

The main purpose of this paper is to discuss certain aspects of nephritis and not to attempt an examination of the whole subject; nothing does away with the necessity of a thorough clinical examination of the patient, in addition to any chemical investigations, in endeavouring to estimate the probable prognosis in a given case. The condition of the cardio-vascular, digestive, respiratory, and nervous systems manifestly demands careful attention. Obviously when renal disease is associated with marked arterial degeneration and high blood pressure the outlook is by no means good, even in cases in which the results of functional tests are more or less satisfactory. The frequency of death from cerebral hæmorrhage in such cases must not be lost sight of, for not infrequently the renal condition is secondary to the cardio-vascular changes.

Treatment.

Apart from the question of general treatment, the dieting of patients suffering from nephritis has always been perplexing and difficult. Recently, however, Epstein[6] suggested that patients suffering from marked œdema or ascites resulting from parenchymatous nephritis should receive a liberal protein diet. He claimed that this treatment resulted in a complete disappearance of the dropsy in many cases. This observation has been substantiated by many observers, and it is now generally admitted that an increase in protein diet is indicated in cases of parenchymatous disease in which dropsy plays a prominent part. In such cases the disappearance of the dropsy which often follows the change in diet is not accompanied by any definite beneficial change in the renal tissue. The amount of protein excreted in the urine is as large as ever, but the patient's general comfort is so greatly increased that he passes from a life of acute suffering to one of comparative ease. This disappearance of the dropsy which so often results from an increased protein intake has been explained by Epstein on the supposition that the lowered plasma protein content is increased, and that consequently a greater osmotic pressure is exerted in the circulatory system; this increased pressure attracts fluid from the tissues to the blood stream, and this fluid is in turn thrown out by the kidneys.

Even if we assume that an increased protein diet does really increase the plasma protein in such cases, it is difficult to understand why this should result in a disappearance of the œdema. On theoretical grounds, indeed, it might possibly be argued with equal force that the result would be an increase in the œdema. Estimation of the plasma protein, however, in several cases of parenchymatous nephritis did not indicate any increase as the result of protein feeding, yet in all these cases the dropsy disappeared. Since this disappearance was always associated with an increase in the blood urea it seems almost certain that the increased excretion of urine in such cases was due to the diuretic action of the urea in the blood.

Action of Urea in Removing Dropsy in Parenchymatous Nephritis.

The fact that increased concentration of urea in the blood accompanies the clearing up of the œdema suggested that possibly urea itself might act in the same way. To test this we have given large doses of urea to several patients with marked ascites and œdema, with the result that in each case the dropsy gradually disappeared. It is hoped to publish details later, and in this connexion it is only necessary to remark here that the treatment, to be successful, must be persevered with for several weeks or even longer if necessary. Thirty grammes or more of urea may be given per day. We generally give two doses of 15 g. dissolved in a little water every 24 hours. Soon the amount of urine passed increases greatly and may be double or treble the ordinary amount. In one case in which this treatment was tried the patient (a female) was absolutely water-logged, and it would be difficult to imagine a more intense œdema and ascites than she exhibited. After a month of urea treatment she began to improve and in three months was quite free from dropsy. She then left the hospital and stopped taking urea. In about a month she returned suffering from both œdema and ascites, which were almost as marked as at the beginning. After a fortnight on urea this cleared up entirely. She was watched for some time and the urea gradually cut off. She is now quite free from œdema and ascites, although she has had no urea for several months.

After-History of Parenchymatous Cases Cured of Dropsy.

Probably the most dangerous variety of chronic kidney disease is that of parenchymatous nephritis accompanied by well-marked œdema and ascites. The tissues become water-logged, and unless relief is obtained the heart and lungs become embarrassed, and the patient dies, we might almost say, from drowning. Although the treatment mentioned above may often succeed in removing the dropsy the renal condition is not influenced, and the proteinuria remains as marked as ever. Though the patient is not cured it is most important to relieve the dangerous dropsical condition, for in the rare cases that survive there seems to be a tendency to pass from the stage in which œdema is one of the most distressing symptoms to one in which the symptoms represent those of chronic interstitial nephritis. When this stage is reached the immediate danger to life is much less and the patient may live in comparative comfort for many years. It is thus most important to prevent the ill-effects of excessive water-logging of the tissues by all means in our power, for if we succeed in keeping the patient alive for some time and get rid of the œdema by appropriate treatment it is reasonable to expect that the condition will change, and the tendency to œdema with its immediate danger to life will in many cases gradually pass over.

The Question of Protein Diet in Interstitial Nephritis.

There does not seem to be any theoretical objection to giving protein or urea in large amounts to parenchymatous cases in which there is no retention of nitrogenous products in the blood. In interstitial cases where such retention tends to be more or less well marked, it is generally considered that protein, especially in the form of meat, is, on the whole, contra-indicated. There is, however, no proof whatever that protein acts detrimentally even in advanced interstitial nephritis, but, on general principles, it is probably best in the present state of our knowledge to limit the intake of protein in patients showing marked retention of nitrogenous products in the blood. This appears to be the general practice, and it is no doubt a good one. On the other hand, it seems quite certain that milder cases of interstitial nephritis are not benefited by very strict dietetic limitations. It is customary for many medical men to order a very strict régime very low in protein content in many cases in which the renal condition is by no means bad. At present many hundreds of men who contracted nephritis on military service, and who still show some albuminuria, are really suffering far more from the effect of low diet than from their renal disease. In the course of the last few months we have seen a large number of such cases in connexion with nephritis work being carried out for the Ministry of Pensions. As the result of very many observations we are convinced that, in general, patients suffering from interstitial nephritis of moderate severity should be allowed a fairly liberal diet in which protein need not necessarily be cut down to any great extent. In very severe cases it is probably best to depend chiefly on carbohydrate food. The whole question of the effect of protein diet in kidney disease still requires much investigation, but it is certain that the custom of feeding patients practically on slops for long periods does more harm than good.

THE FACTOR OF FEVER IN THE DIAGNOSIS OF CANCER.[1]

BY W. GORDON, M.A., M.D. CANTAB., F.R.C.P. LOND.,
PHYSICIAN TO THE ROYAL DEVON AND EXETER HOSPITAL.

GENERALLY speaking, fever is uncommon as an accompaniment of cancer; its chief importance depends on the liability to forget it. If fever be forgotten, cancers may be diagnosed as inflammatory lesions, and inflammatory conditions secondary to cancers may have their cause overlooked. The practical problems which present themselves in connexion with fever in cancer are three: 1. If fever is present, is it caused by uncomplicated cancer? 2. If cancer is present and fever also, is the fever due to the cancer itself or to some inflammatory complication? 3. If an inflammatory lesion is present, causing fever, is cancer also present?

Some years ago it was taught that uncomplicated cancer is necessarily afebrile. Thus, so lately as 1895 a well-known writer on diseases of the stomach committed himself to the statement that "uncomplicated cancerous disease does not of itself produce fever." And this teaching, though not universal, has done much to create a general impression which persists. There is now, however, evidence that rapidly growing cancers, such as round-celled sarcomata and the softer varieties of carcinoma, in certain organs, can cause fever in the absence of an inflammatory complication. This seems to be the case in six situations at least—viz., in the liver, stomach, suprarenals, long bones, lungs with mediastinum, and breast. But precise evidence, so far as I can discover, is limited to cancer of the liver, the stomach, and the long bones. Evidently the subject needs closer attention than has yet been given to it. However, the following three statements seem to me to establish the fact that it occurs.

Sir Humphry Rolleston writes that amongst cancers of the liver cases occur accompanied by fever, as in some instances of primary malignant disease of the organ, in which no other cause for the fever than rapid cell-growth is forthcoming. Dr. Soltau Fenwick, speaking of the softer varieties of carcinoma associated with fever (primary growths, of course), says that in 8 per cent. of them the growth was not associated with any complications visible to the naked eye. My colleague, Mr. B. Dyball, tells me that he has had a case of sarcoma of the tibia in which the temperature was constantly between 100 and 101° F. in absence of any inflammatory complication.

I propose to call this fever of cancer uncomplicated by inflammatory lesion "growth fever," a name which only commits us to the assumption that the fever is produced by some process of the growth itself, apart from inflammation; and to term the fever caused by any inflammatory complication of a cancer "complication fever."

In what I have to say no reference will of course be made to such independent intercurrent febrile disorders as may attack cancer patients, just as they may attack anyone else—influenza, typhoid, &c. Nor shall I lay much stress on terminal fever, due to some final complication, preceding death by but a few days, although I shall allude to it where it may occur; such terminal temperatures do not help us much in the matter of timely diagnosis. I shall avoid reference to my own personal experience except in a very few instances, since opinion on this subject must be formed upon a wider basis.

What I have termed "growth fever" has hitherto been explained as "due to the rapid growth and multiplication of the cells," to "an extreme activity of cell growth." This may well be the cause. But there are other possibilities which have to be considered. The following suggestions have been put forward by some of my colleagues with whom I have discussed the subject. Mr. A. L. Candler points out that in a rapidly growing cancer the vitality of the new cells is low, and suggests that the fever may be due rather to absorption of dead material than to activity of growth. In support of this idea Mr. A. C. Roper recalls a case in which a mass of inoperable glands in the neck was submitted to the X rays, with the result that the temperature went up to 103°, a condition of fatal toxæmia being established, seemingly from excessive destruction of cancer cells. Mr. N. F. Lock makes a different suggestion, that, as in rapidly growing cancer hæmorrhage is common, the absorption of this blood may account for the fever.

---

[1] A paper read at a meeting of the Devon and Exeter Medico-Chirurgical Society, April 22nd, 1920.

Classification of the Conjunction of Fever and Cancer.

I will classify cancers according to the type of fever occasionally found in conjunction therewith:—

A. *Either growth fever or complication fever.*—Liver,* stomach,* suprarenals,* lung with mediastinum, long bones, breast (rarely).

B. *Complication fever only.*—Gall-bladder,* bile-ducts,* large intestine,* small intestine,* appendix,* uterus,* fallopian tubes,* ear,* glands in neck,* tongue, lip, œsophagus, pancreas, peritoneum, rectum, eye, larynx, thyroid.

* Commonly.

C. *Neither form of fever.*—Kidney, ovary, vulva, testis, penis, urethra, parotid, jaw, brain, spine, skin, muscles, heart and pericardium.

Group A.—Cancers accompanied by either "Growth Fever" or "Complication Fever."

Liver.—"Growth fever" is said to be more common in cancer of the liver than in cancer of any other organ. At all events it is not uncommon in primary carcinoma and sarcoma, especially in the rapidly fatal sarcomata of young persons. The temperature generally reaches 101°, and seldom exceeds 102°. It may continue for weeks. The diagnosis of such cancers from abscesses, says Rolleston, may only be possible on exploration, especially in children and young adults. The difficulty is increased by the occasional breaking down of the tumour with the formation of cysts. In quickly-growing secondary sarcomata and carcinomata of the liver "growth fever" may also occur; but here the presence of a primary cancer elsewhere, with perhaps an open ulcer, renders the source of the fever uncertain.

"Complication fever" may be caused by the following complications of hepatic cancer: abscess (single or multiple), suppurative cholangitis, suppurative pylephlebitis (very rare), empyema (rare), ulcerative endocarditis (very rare). So when we diagnose the presence of one of these lesions, though cancer may not be obvious, we have to remember that either a hepatic cancer, or some other cancer to which a hepatic cancer may be secondary, may be the cause thereof.

It is necessary also to recall in our diagnosis the other febrile hepatic diseases, besides those just enumerated, which must be diagnosed from febrile cancer; and to remember that many diseases of the liver may be associated with fever. Syphilis with gummata may, in the liver, set up a temperature just as cancer may do. Portal cirrhosis is occasionally febrile in its earlier stages, especially in young patients, apart from its febrile complications. The temperature may range from 100 to 102·5°. Biliary cirrhosis (less likely to cause difficulty, from the earlier age and the history) is generally accompanied only by febrile exacerbations with abdominal pains and temporary increase of jaundice. Gall-stones may cause either "intermittent hepatic fever" or the more continuous high temperature of their complications. Abscess, and acute hepatitis short of abscess, may cause a high and swinging temperature with rigors. Lymphadenomatous enlargement of the liver may be associated with the peculiar oscillating and undulatory fever of certain cases of that disease. Lastly, infective jaundice, actinomycosis, suppuration hydatid disease, and massive tubercle have to be borne in mind.

Stomach.—"Growth fever" appears to occur in a certain number of cases of cancer of the stomach, seemingly most often in sarcomata, especially in young persons, and in the softer varieties of carcinoma which are often met with on the walls of the organ as distinguished from the orifices. This fever may be present throughout the whole course of a round-cell sarcoma. It is usually continuous and ranges from 99 to 102°. Taking both sorts of fever together, Fenwick finds that a third of all cases of gastric cancer have fever at some part of their course, and he points out that sometimes this fever is so prolonged and severe as to cause serious mistakes in diagnosis; of the cases which have fever about half have it constantly. Osler and McCrae found fever in half their cases, and constant fever in a fifth of this half.

When even occasional fever is present throughout the course of a gastric cancer, chills are common, in which the temperature may rise as high as 102 or 103° and remain up for two or three days. When the fever is continuous the temperature is generally, Fenwick says, between 99 and 100° in the morning and between 100 and 101° in the evening. Occasionally the morning temperature is subnormal, so that the chart resembles that of suppuration. Either of these types may last for months. Towards the end the fever is apt to cease. In rare cases the fever is constantly over 100° and shiverings and sweatings accompany it.

The complications of gastric cancer capable of causing fever are: general peritonitis from perforation, in about 3 per cent. of the cases; local peritonitis, also in about 3 per cent., producing subdiaphragmatic abscess, generally below the left wing of the diaphragm, abscess between the stomach and the anterior abdominal wall, or some small pocket of pus elsewhere; abscess of the liver, spleen, or kidney from direct invasion of one of those organs—these are rare, especially the last; suppurative pylephlebitis is very rare.

It is noteworthy that, apart from perforation of a gastric ulcer and the very rare cases of phlegmonous gastritis, gastric diseases are not attended by fever. Hence considerable fever in connexion with gastric disease, but in absence of evident complications, may suggest the presence of some form of rapidly growing cancer.

Suprarenals.—Cancer of the adrenals seems to be very commonly associated with considerable irregular fever, and Dock goes so far as to state that this occurs in half the cases. Such fever appears to be "growth fever," for I can find no statement that inflammatory complications in any case account for it. It is worth calling to mind that acute adrenal hæmorrhage is a markedly febrile disease.

Lungs and mediastinum.—"Growth fever" seems to account for some of the febrile cases reported, since a single large lung tumour may produce fever apparently without inflammatory complications. I remember seeing many years ago, with Dr. Alfred Perkins, an old postman suffering from what resembled acute rheumatic fever, with considerable temperature, sweating, and a rapid very feeble heart. On autopsy a primary cancer of the lung was found on the left side, beginning in the root of the lung and extending upwards and backwards to reach the pleura under the supraspinous fossa; no inflammatory complication was discovered.

All authors describe a rare and remarkable form of pulmonary cancer which runs an acute course of something under three months, with rigors, fever, sweatings, and rapid emaciation, the temperature reaching 102 or 103°. Such cancers have been mistaken by good observers for caseous pneumonia. The presence of moderate and irregular fever in a pulmonary case, coupled with the pressure symptoms which pulmonary tumours exert, has been held to point towards cancer. More often probably fever in lung cancer is due to complications. These are empyema, abscesses in the lung from blockage of bronchi, cavities, associated broncho-pneumonia.

The same remarks apply to cancer of the mediastinum, often not easily distinguished clinically from pulmonary cancer, where, according to Sir R. Douglas Powell and P. Horton-Smith Hartley, pyrexia of a low irregular type is often present; but in such cases the growth is rarely found at autopsy to be uncomplicated, "broncho-pneumonia" or a slowly disintegrating form of septic broncho-pneumonia being most often discovered. W. H. Walshe met with complicating empyema on the side most affected at least six times. In lung and mediastinum the curious paradox arises that where the diagnosis lies between cancer and an acute or subacute inflammatory consolidation or effusion, in which fever is practically invariable, absence of fever would suggest growth; whilst in cases where the question lies between cancer and a very chronic condition, like some chronic pneumonias, in which fever is generally absent, fever would suggest cancer.

Long bones.—Sir H. Butlin and Dr. Colby in 10 cases of various kinds of sarcoma of the femur found constant fever in 5, habitually 100° in most of them, and 102° in one case up to the time of amputation. So far as one can discover from the meagre details, these cases appear to have been uncomplicated. These authors note the difficulty in diagnosis caused by the rise of temperature, but do not definitely state whether inflammatory complications did or did not exist. Mr. Dyball, as mentioned above, has seen a case of sarcoma of the tibia in which the temperature was constantly between 100 and 101°, with no inflammatory complications.

Breast.—"Growth fever" is definitely stated to occur in rare and rapid cases of primary breast sarcoma. And by inference it seems likely that such cases of rapid sarcoma and carcinoma as "simulate abscess" are febrile; but I cannot find this stated. "Complication fever," one imagines (again it is not stated), would accompany the abscesses which rarely form in connexion with breast cancer.

Group B —Cancers accompanied by "Complication Fever" Only

Uterus —Pyometria may occur in either cancer of the body or cancer of the cervix When pain has come on and the uterus is fixed, W J Sinclair finds fever at night (100° or a little higher) constant, and attributes it to parametritis or septic absorption Later on, he says, occasional fever may be higher still Pelvic peritonitis, pyosalpinx, and abscess of the ovary are all rare events

Fallopian tubes —Pyosalpinx seems common in this very rare disease

Tongue —Butlin stated that tongue cancers "set up suppuration round them and in the neighbouring glands"

Larynx —P Watson Williams and Sir Felix Semon tell us that 'secondary perichondritis which may proceed to suppuration and exfoliation of cartilages, not infrequently complicates the disease and may quite obscure its objective symptoms"

Thyroid —Remittent fever is not uncommon in the later stages according to G Dock, but he makes no mention of suppurative complications

Œsophagus —Periœsophageal abscess may be set up, or empyema, or pulmonary gangrene All are unusual It may be of interest to mention a case of pulmonary gangrene caused by an œsophageal perforation from cancer, where my colleague, Dr R V Solly, found in the fluid an organism at least closely resembling the Oppler Boas bacillus

Small intestine —Duodenal cancer when it involves the biliary papilla, typically ends, Rolleston tells us, in cholangitis Cancer of the jejunum or ileum may cause fever and tumour so as closely to simulate appendicitis

Appendix —Cancer of the appendix causes an attack just like appendicitis, and the nature of the case is only discovered after operation My colleague, Dr Ransom Pickard, gives me a good instance of this

Colon —The complication to be expected here, causing fever, is peritonitis, general or local General peritonitis is common Abscess is not uncommon, and may arise without perforation Cancer of the cæcum may thus simulate appendicitis My friend, Mr Russell Coombe, considers that a moderate temperature is a very common accompaniment of these growths, especially of cancer of the sigmoid

Rectum —Local abscess or general peritonitis may occur

Peritoneum —Extensions of the cancerous implantation appear to cause temporary rises of temperature

Gall bladder —Here empyema of the gall bladder, suppurative cholangitis, suppurative pancreatitis, local peritoneal abscess general peritonitis, and ulcerative endocarditis have all been recorded

Bile ducts —Suppurative cholangitis with or without miliary hepatic abscesses, is common, and ulcerative endocarditis may arise

Ear —The greatest difficulty in diagnosis may be caused by suppuration, which in these growths is scarcely ever absent

Eye —Intra ocular suppuration may be a sequel of intra ocular growth Meningitis may also occur

Pancreas —It is curious that so little reference can be found to fever in connexion with cancer of the pancreas But Mr Dyball tells me he has met with a case in which fever was caused by suppurative cholangitis secondary to carcinoma of the head of the gland

Prostate —It would be interesting to know if "growth fever" accompanies the rapid sarcomata of this organ Fever begins in ordinary cases of cancer when cystitis is set up

Bladder —Mr Dyball tells me that fever begins with cystitis

Glands in the neck —My colleague, Mr Roper, calls my attention to the frequency with which suppuration is associated with large secondary glands in the neck

Group C —Afebrile Cancers

It is not improbable that once sufficient attention has been given to the occurrence of fever in cancer and to its importance in diagnosis some of the cancers which I am now going to enumerate may be found occasionally to cause fever From the accounts, however, to which I have been able to gain access neither "growth fever" nor "complication fever" occur in them A few present, it is true, a terminal fever, such as a final brief septic pneumonia in parotid cancer, but such fever has little value from a general diagnostic standpoint

Kidney —I have never seen fever in kidney cancer, and can find no account of its occurrence The fact is curious in view of the rapid growth of renal sarcomata in children Surely, at least in those cases where pyonephrosis arises from obstruction by the growth, some fever may be present If not, a tumour in the renal region associated with fever should presumably be suprarenal But if so, what happens in cases of renal hypernephroma?

Urethra —One wonders whether periurethral abscess ever occurs The growth is excessively rare I have seen one case which was cut into on the supposition that it was an abscess, but I do not remember any fever

Ovary —Here growth may be rapid, and one wonders if "growth fever" occurs

Jaw and parotid —Both growths may exhibit a terminal fever from septic broncho pneumonia Otherwise, I can find no reference to fever

Other growths —Of the other growths in the list given above I have nothing to say, except that I can find no record of their producing fever

Conclusion

I am very sensible of the shortcomings of this paper. They seem inseparable from a subject to which too little general attention has been attracted If my remarks succeed in arousing more interest in what appears an important factor in cancer diagnosis, and especially in that form of fever which I have called "growth fever," my object will have been attained.

CEREBRAL REACTIONS FOLLOWING INJECTIONS OF NOVARSENOBENZOL

WITH A RECORD OF TWO FATAL CASES.

BY FREDERICK G HITCH, M B, B S LOND, M R C S, L R C P,
SURGEON LIEUTENANT COMMANDER R N SPECIALIST IN VENEREAL DISEASES ROYAL NAVAL HOSPITAL CHATHAM

THERE has been much discussion as to the cause of the severe cerebral reactions, usually ending fatally, which from time to time occur during the treatment of syphilis with arsenical preparations of the salvarsan and neosalvarsan type, and up to the present no general agreement on the subject has been reached It seems, therefore, important to publish any cases in which the symptoms or pathological findings may be helpful.

The two cases here recorded may be regarded as typical Both patients were well developed young adults, apparently healthy except for their specific infection, and presented neither in their past history nor present physical condition any of the recognised contra indications to arsenical treatment, both developed the usual symptoms of epileptiform convulsions and coma, and both terminated fatally

CASE 1 —This patient, aged 29, was admitted to the Royal Naval Hospital, Chatham, Dec 18th, 1919 with a primary sore situated within the left nostril, a papular and roseolar rash, and generalised enlargement of the lymphatic glands of the body *S Pallida* was demonstrated in abundance in the intranasal sore by dark ground illumination and the Wassermann reaction in the serum was positive On Dec 22nd 0 45 g novarsenobillon was given by intravenous injection of concentrated solution No reaction followed On Dec 29th a second injection of 0 6 g was given A slight "endotoxic" reaction followed indicated by a rise of temperature to 101 2°F the same evening, falling to normal level next morning The unusually long interval of seven days between the injections is due to the Christmas holidays On Dec 31st, in the morning, the patient's temperature was 99°, but normal in the evening He complained of slight headache and appeared nervous and apprehensive as to his condition but on examination no cause for alarm was found During the night, however, the signs of severe cerebral reaction developed, the patient became completely unconscious, the teeth were tightly clenched, and the jaws could only be opened with difficulty Almost continuous convulsive movements of the limbs and facial muscles, suggestive of extensive cortical irritation were present, and continued until a few hours before death Incontinence of urine occurred The pulse was rapid, 140 to 150 per minute, equal, regular, and not of high tension The temperature at first normal, rose to 103 4° before death, but hyperpyrexia was not observed as in the case following Urine withdrawn from the bladder by catheter about 12 hours after the onset of the symptoms was found to contain albumin and blood The respirations were at first frequent, 40 to 50 per minute, deep and stertorous, but later on, as the respiratory centre was becoming exhausted, became gradually slower, shallower, and weaker, and at times the breathing took on a Cheyne-Stokes character A moderate degree of cyanosis was present, temporarily relieved by inhalations of oxygen The patient died at 12 25 P M on Jan 2nd without regaining consciousness, death being apparently due to failure of the respiratory centre

CASE 2.—A Jew, aged 22, was admitted on Dec. 4th, 1919, with a healed chancre at the base of the penis, a well-defined macular secondary rash, ulceration of left tonsil, and general glandular enlargement. The Wassermann reaction in the serum was positive (Dec. 6th). No contra-indications to arsenical treatment were discovered, and treatment with intravenous injections of novarsenobillon in concentrated solution was commenced. Three doses, beginning with 0·45 g., were given, and were followed by no reactions. A fourth dose (0·6 g.) was administered on Dec. 15th, and 48 hours later the cerebral symptoms appeared. The patient at first complained of slight headache and sore-throat, his temperature being 99·2° F. About ten minutes after being seen the patient suddenly became unconscious and fell into an epileptiform seizure, followed by convulsive movements of the limbs as in the first case, and these continued until a few hours before death. Incontinence of urine occurred. The pupils were equal and contracted; the corneal reflex was not lost until shortly before death. The pulse was rapid, 140 to 150 per minute, but of good volume and moderate tension. Respirations were rapid, deep, and stertorous, but later, as the respiratory centre became exhausted, shallow, feeble, and irregular. Cheyne-Stokes breathing was not observed in this case. A moderate degree of cyanosis was present. The temperature commenced to rise shortly after the onset of symptoms and hyperpyrexia supervened, the axillary temperature rising to 107·4° four hours after the onset of symptoms. Death occurred 11 hours after the onset of the reaction and was apparently due to failure of the respiratory centre.

Treatment.

The treatment of these cases was on orthodox lines and was apparently quite useless. In the first case lumbar puncture was performed and about 25 c.cm. of clear fluid not under abnormal tension were withdrawn. Adrenalin, 1 c.cm., was given hypodermically at the outset, and was repeated later with no apparent benefit. Normal saline solution was injected intravenously, also saline and brandy per rectum. When the cyanosis became marked inhalations of oxygen were given, and, in view of the conclusions drawn later, it is regretted that its continuous administration was not adopted. In the second case, in addition to these measures, 20 ounces of blood were withdrawn from the median basilic vein, and cold sponging and an ice-cap were applied in order to combat the hyperpyrexia. In this case, also, no benefit whatever resulted from the injection of the adrenalin, although it was given freely. The advisability of giving this drug in these epileptiform conditions may be called in question by the experience of Benedek,[1] who gave injections of 1–1·5 c.cm. of suprarenal extract to 19 epileptics, and found that seven of these developed a typical seizure from a half to one and a half hours after the injection.

Autopsies.

At the post-mortem examination in each case the most striking naked-eye pathological change was extreme congestion of the lungs, the condition being most marked at the bases. The lower lobes appeared heavy, dark, and deeply engorged with blood; in places they were airless, and on section dripped blood-stained serum.

In Case 2 no other pathological condition was apparent to the naked eye. There was no abnormal meningeal congestion, and no disseminated punctate hæmorrhages, as described by various observers, were visible in the brain substance. The liver, kidneys, spleen, and other viscera presented a natural appearance.

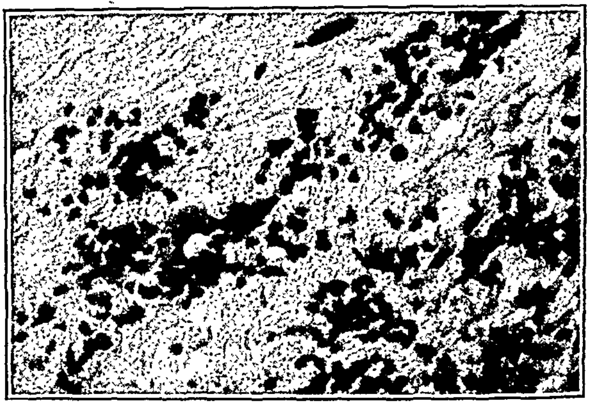
In Case 1 changes were also observed in the brain and liver, that in the latter organ being probably of post-mortem origin, and consisting of irregular yellowish patches scattered over both lobes and extending about 0·5 cm. below the surface. The meninges appeared healthy, but over the cortex of the cerebrum, especially of the temporal and occipital lobes, the smaller vessels of the pia arachnoid appeared slightly congested. On section the brain appeared normal to the naked eye, with the exception of the optic thalami, especially the right, in which there seemed to be some extravasation of blood from the smaller vessels. The choroidal plexuses were not engorged, and the ventricles contained no excess of fluid. The kidneys presented no appearance of congestion or inflammation, in striking contrast to the pictures seen in the microscopic sections. No pathological changes were noted in the other viscera.

A complete investigation as to the presence of arsenic in the various organs was not carried out, and in view of the rapid elimination of novarsenobenzol, little or no information would be gained thereby. Marsh's test was performed for the presence of arsenic in the brain of the first case, but a negative result was obtained.

Microscopic sections were made of the lungs, kidneys, optic thalamus, and liver of the first case.

Lungs: Sections were made through the deeply congested portions, and stained with hæmatoxylin and eosin and by Heidenhain's iron-hæmatoxylin method. They presented a striking appearance, characterised by interalveolar, and especially interstitial, bleeding from the capillary vessels. Some proliferation of the cells of the epithelial lining of the alveoli, with shedding of the so-called "catarrhal" cells, was also shown. The smaller bronchioles were filled with red blood cells. The most striking feature was the pronounced interalveolar bleeding.

Optic thalamus: Sections were cut through the hæmorrhagic area, and similarly showed extensive capillary hæmorrhage, the blood from the ruptured capillaries lying between the nerve fibres and cells.



Section of optic thalamus stained with iron-hæmatoxylin, showing extravasation of blood between nerve fibres.

Kidneys: In these organs, also, capillary bleeding was the outstanding feature of the sections. The selective action of the toxin causing the condition was well shown, for while the glomerular tufts presented a normal appearance, there was widespread extravasation of blood into, and especially between the tubules from the capillaries of the tubular portion of the organ.

Liver: Sections were made through the areas of discoloration observed at the post-mortem examination. Here, also, capillary hæmorrhages were present, although the bleeding was not so widespread as in the other organs examined.

The feature common to all these sections is therefore the extravasation of blood from injured and ruptured capillaries, the interalveolar bleeding in the lungs being especially remarkable.

On the Causation of Symptoms.

Several hypotheses have been advanced to account for the production of the condition under consideration, and at present that of G. Milian, attributing the symptoms to the vaso-dilator effects of the arsenical preparation acting in a patient with diminished suprarenal activity, is the one most widely accepted. The treatment of the cases by adrenalin given in various ways has been recommended by many authorities. The condition is known by the supporters of this theory as "serous apoplexy." An interesting résumé of the subject is given in *Medical Science* for January, 1920, where some interesting cases are quoted in support of and against Milian's explanation.

Surgeon Lieutenant Commander R. J. G. Parnell,[2] R.N., has recently recorded an interesting case which recovered after the intravenous injection of urotropine and the continuous administration of oxygen, and Surgeon Commander Sheldon F. Dudley, R.N., in a note appended to his paper, advances the opinion that these cases are probably accompanied by anoxæmia, possibly of the type described by Professor J. S. Haldane[3] as due to the alteration of the dissociation curve of oxyhæmoglobin, so that it gives off oxygen less readily in the tissues.

The post-mortem appearances in the two cases here described appear strongly to support Surgeon Commander Dudley's contention, but I would rather refer the production of the anoxæmia not so much to the alteration of the dissociation curve of oxyhæmoglobin but to another condition stated by Professor Haldane[4] to be a factor in causing anoxæmia—that is, defective saturation of the arterial blood with oxygen, owing to swelling, exudation, or other abnormality in or around the alveolar walls, preventing the diffusion of oxygen inwards quickly enough to saturate the blood in the limited time during which it passes through the alveolar capillaries.

The swelling or shedding of the lining cells of the alveoli and the widespread interalveolar and interstitial hæmorrhage seem quite sufficient to bring this about, and the capillary bleeding in the brain and other organs would further prevent the tissues from obtaining their requisite amount of oxygen from the already anoxæmic blood. The same process taking place in the kidneys, acting in the same way, would be a sufficient cause of the anuria or albuminuria described in many cases and attributed to the direct toxic action of the arsenic. The forced breathing, rapid, deep, and stertorous, which occurs in these patients would also tend to increase the degree of anoxæmia.[5]

Conclusion.

The conclusion arrived at is that the widespread capillary hæmorrhages, demonstrated by microscopic sections, afford a clear anatomical basis for the hypothesis put forward by Surgeon Commander Dudley that the symptoms are due to anoxæmia, that this anoxæmic condition is mainly produced by interalveolar hæmorrhage into the lungs, and to a less extent by interstitial capillary bleeding into other organs, and that the *continuous* administration of oxygen as carried out by Surgeon Lieutenant Commander Parnell offers the best hope of recovery in these unfortunate cases.

These appearances would also seem to explain in part the rapid development of the symptoms and the comparatively slow recovery, as instanced by Surgeon Lieutenant Commander Parnell's case, resulting from the continuous administration of oxygen.

I wish to express my thanks to Surgeon Commander E. L. Atkinson for his kind assistance, especially in preparing the accompanying photomicrograph.

TRAUMATIC RUPTURE OF THE HEART

BY R. K. HOWAT, F.R.C.S. ENG.,
HONORARY SURGEON, NORTH RIDING INFIRMARY, MIDDLESBROUGH

TRAUMATIC rupture of the heart is generally due either to gunshot or to stab wounds. These being commonly received in front, one or other of the right chambers of the heart is the usual site of the rupture. Such ruptures, where not immediately fatal, offer a prognosis distinctly better than do spontaneous ruptures. The wound in the pericardium permits the escape of blood from that sac and so diminishes the risk of rapidly fatal embarrassment of the heart's action; the circumstances of the case, the site, and direction of the wound in the body wall make diagnosis less difficult and so facilitate treatment, and the patient and his heart tissue are often healthy. That such ruptures of the heart have been recovered from, with and without operative treatment, is familiar enough.

An Unusual Case.

The following case is of interest for two reasons—because of the nearly complete absence of skeletal and superficial injury following upon extreme violence and because of the unusual nature and circumstances of the heart's rupture.

A well built, healthy shipwright, aged 23 years, sustained a clean, unbroken fall of 45 feet, alighting on a wooden plank and some steel plates lying on the ground. The precise position of his body at the end of the fall was not known. He was not killed outright, but was dead on his arrival at hospital some 20 minutes later.

On post mortem examination of the body about six and a half hours after death rigor mortis had not begun. Preliminary inspection revealed no damage beyond a few scratches and bruising at the right elbow. A deliberate examination by inspection and palpation showed no further evidence of bruising, laceration, fracture, or dislocation. The peritoneal cavity contained about 2½ to 3 pints of fluid blood, of which the source appeared to be five transverse lacerations of the right lobe of the liver—four on its upper, one on its under surface immediately to the right of the transverse fissure. There was a considerable quantity of blood effused into the retroperitoneal tissue. There were two transverse tears about half an inch apart on the front of the right kidney near its middle, one through little more than the capsule, and one about ¼ inch in depth through practically the entire width of the kidney. No other source of retroperitoneal hæmorrhage was found. No other abdominal injury was discovered.

I failed to identify the source of a moderate extravasation of blood into the cellular tissue of the posterior mediastinum. This blood extended to the back of the root of each lung underneath the pleura, but not into the substance of either lung, which, indeed, appeared to be normal throughout. The pericardium was intact and contained about a pint and a half of fluid blood. After considerable search a slit like opening into the cavity of the left auricle was found, about a quarter of a centimetre in length, and situated exactly in the length of the free edge of the left auricular appendage.

Professor S. G. Shattock kindly made a microscopical examination of the appendage wall, and reports that there is no trace of any form of disease.

Remarks on the Case.

The height above the ground of the planks from which deceased fell was 45 ft., and the fall was unbroken. The injuries were thus caused by the violent impact of the body against the plank and plates on the ground. The visceral injuries, and particularly the fact that the ruptures in the liver and right kidney were transverse in direction, suggest antero posterior compression of the trunk, and the complete absence of bruising of the body wall is remarkable. It would seem on first thought almost incredible that such a fall should occasion no injuries other than visceral. It is probable, however, that such cases are not so very uncommon, and it is therefore important that they should be recorded, as the question is one of considerable legal importance.

In this case the nature and accompanying conditions of the cardiac rupture raise questions as to the mode of its production. Cases of cardiac rupture are commonly divided into two classes, spontaneous and traumatic. The former occur from within because a local weakness of the heart's wall renders it there unable to withstand the pressure of the contained blood. Such local weakness is most commonly the result of disease, and its favourite seat is the left ventricle. Spontaneous rupture of the entire thickness of the heart's wall is rapidly and, doubtless, invariably fatal, because the shed blood, accumulating within the intact pericardium, quickly embarrasses the heart's action to the point of stoppage, and because it is practically impossible to diagnose and so directly treat the condition in the short time available. That spontaneous rupture of a quite healthy heart ever occurs may be doubted. A cautious reference to a possible case of this is given in Wilks and Moxon, "Pathological Anatomy" (p. 120).

Delayed Traumatic Rupture of the Heart.

But there are cases of traumatic rupture of the heart without wound of the pericardium, and these tend to resemble cases of spontaneous rupture in their rapid course. Again, trauma may cause injury of the heart's wall without immediate rupture, but after an interval the injured area may prove the site of a rupture, which may be described as "delayed traumatic" or "spontaneous" according to predilection. Where the interval between the receipt of injury and death is considerable difficult questions about the cause of death may be raised by claims for monetary compensation or damages for fatal accidents.

An excellent illustrative case of delayed traumatic rupture of the heart has been described to me by my colleague, Dr. J. Donaldson, as occurring in his practice.

The patient was a bricklayer, aged 68, unusually deep chested, who enjoyed good general health. He was working beside a large iron pipe close to which were the rails on which bogey trucks ran. On the approach of a truck he stood with his back pressed close against the pipe in order that the truck might clear him. Owing to his depth of chest the truck which had cleared others just failed to clear him, and squeezed the front of his chest, scraping the skin, but doing no further apparent local injury. He was in bed for two weeks and resumed work after three weeks. His pulse rate showed no departure from the normal, and his general condition called for no special remark or anxiety. After three days' resumption of work he felt unable to continue, his chief complaint being pain in the chest. He was confined to bed again for two weeks, during which his pulse-rate rose gradually from 30 to 60. He appeared to be progressing favourably when he suddenly died. A post-mortem examination revealed no injury of any part of the chest wall, except the scraping of the skin. The pericardium was intact and full of blood. No disease of any part of the heart substance was found. The left ventricle alone was injured. Its wall was bruised in five places, three in front and two behind. The largest bruise, the size of a shilling and extending through the greater part of the wall's thickness, was in front near the apex. Here the ventricle wall was ruptured.

Results of Pressure.

Traumatic rupture of the heart within an intact pericardium is almost certainly due either to compression or concussion. Pressure may act in two ways. It may either directly injure the heart tissue (by bruising) so that the injured part gives way immediately or later, or else, without directly injuring the heart tissue, it may so raise the intracardiac blood pressure that the healthy heart wall is burst from within. Compression depends on the amount of force, concussion on the rapidity of its application. In Dr. Donaldson's case the circumstances suggest that compression alone was operative, the heart being squeezed between the front and back of the thorax. Professor Shattock has been kind enough to inform me of three cases of traumatic rupture with intact pericardium. Two of these are among the "gunshot" injuries from the seat of war in the Royal College of Surgeons of England.

In one (specimen No. 657) there was a shell wound of the skin in the left midaxillary line, comminuted fracture of the fourth and fifth ribs, and laceration of the left lung. The anterior wall of the left ventricle shows a vertical perforation occupied by clot in which no missile was found, and no wound was found in the pericardium. The interval between the times of wound and death is not mentioned. Such an injury points to contusion of the heart wall by the broken ribs acting through lung tissue and pericardium. Its mode of production also permits of the action of concussion. The latter factor may have been still more operative in the other gunshot case (specimen No. 486) in which there was a non-penetrating wound of the thoracic wall, without fracture of ribs or sternum, the pericardium was found distended with blood, and the anterior wall of the right ventricle showed a minute rupture. In the third case, related to Professor Shattock by Mr. C. F. Beadles, a lunatic was struck on the chest with a spade. A rupture of the heart was found without fracture of bone.

In these two last cases, as in that of the shipwright, the circumstances suggest that concussion, as distinct from compression, *may* have played a part. But what that part amounted to it is impossible to calculate. In the shipwright's case the fact that the heart wall showed no sign of injury except the rupture itself indicates that pressure probably operated through its effect on the blood within the left auricle. This would be most effective when the auricle was at its maximal distension; and the site of the rupture suggests that the incidence of the pressure on the distended auricle has been such as to tend to drive the contained blood away from the natural openings and towards the blind extremity of the chamber.

PROPOSED HOME FOR INVESTIGATION AT HARROGATE.—The establishment at Harrogate of a clinic for the investigation (as opposed to the prolonged treatment) of chronic diseases and of disorders of metabolism, on lines similar to those of the well-known Duff House, Banffshire, is in process. Suitable premises are being adapted to accommodate 30 beds in the first instance, further extensions being made as the need arises. The staff will consist of a resident physician, visiting physicians and surgeons, a radiologist, and a pathologist. Certain members of a fully trained nursing staff will be detailed to control the department of dietetics. Special lines of investigation will be undertaken as opportunity offers, and the results will be collated and published from time to time. It is stated that the scheme is to be constituted as a limited liability company nuder the management of a board of directors, on which the medical profession is to be represented in sufficient numbers to ensure that the institution is conducted on lines conformable with professional requirements and traditions.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

CONGENITAL STENOSIS OF THE AORTA.

BY R. O. MOON, M.D. OXON., F.R.C.P. LOND.,
PHYSICIAN, NATIONAL HOSPITAL FOR DISEASES OF THE HEART, WESTMORELAND STREET, W.

THE special points of interest in this case are the very few symptoms calling attention to the heart, combined with the pronounced physical signs and the comparatively slight impairment of the boy's general activity.

D. R., a boy, aged 11 years, came as an out-patient to the Heart Hospital in March, 1919, *complaining of "headache, looseness of the bowels, and some recent epistaxis."* There was nothing of importance in the family history. During the first 18 months of his life he had apparently been somewhat delicate, and in the early *weeks of infancy his mother said that "he had seemed to strain for* breath at times," but had never been taken to a doctor for it. When 18 months old he had measles and shortly afterwards he was taken to the Children's Hospital, Kensington, when the parents learnt for the first time that his heart was diseased.

At the age of 3½ years he is said to have brought up a large quantity of blood, which seems to have been vomited, and was taken to St. Mary's Hospital, where he remained for six weeks and "congenital morbus cordis" was diagnosed, a thrill over the aortic area and a basic systolic murmur being specially noted. After this his general health remained good apart from occasional attacks of epistaxis. He would, however, often complain of headache and have to stay away from school for a day or two on that account. He was always active and energetic and could always walk a fair distance and even play football without becoming breathless or tired, though he got breathless sooner than other boys. In general appearance he was distinctly undersized, very pale, but bright and intelligent-looking. The apex beat was in the fifth space in the nipple line with a somewhat forcible cardiac impulse and the dullness a trifle increased to the left. Over the aortic area there was a very coarse systolic thrill, which was also palpable over the carotid arteries. All over the præcordial area there was a harsh systolic murmur, having a maximum *intensity at the second right* interspace, where it could be heard several inches from the chest wall. Pulse was small in volume, rate 70.

The X rays showed nothing abnormal, but in the electrocardiogram the T-wave was *inverted in Leads II. and III.*, while in Lead III. the P-wave was inverted. There was no evidence of left-sided preponderance. The Wassermann reaction was negative. The boy was brought back to the hospital six months later, feeling quite well, for permission (which was given) for an anæsthetic for the removal of teeth. Some three weeks later I heard that he had died quite suddenly at school, having seemed perfectly well in the same morning.

Dr. K. E. Eckenstein, who did the post-mortem, found a much enlarged thymus gland. Lungs, liver, spleen, and kidneys were normal. The heart weighed 8½ oz. Thickness of left ventricular wall 3-3·5 cm.

Professor Sir G. Sims Woodhead kindly made a special examination of the heart for me, and his report is as follows:—

> There is well-marked evidence of old endocarditis on the left side, though little on the right side. The aortic cusps are enormously and irregularly thickened, "cartilaginoid," rigid and adherent at the angles, with rounding and retraction at the margins. During life, owing to stenosis, this must have given rise to marked interference with the passage of the blood from the ventricle to the aorta with, in all probability, a certain degree of regurgitation through incompetence from the rigidity of the valves and thickening and irregularity of their margins. At one point near the edge, and apparently at the junction of two cusps, is a slightly more recent fibrous mass, which seems to me to be an indication that the process of cicatrisation and fibrous tissue formation has been going on intermittently for a considerable period. At the base of the mitral flap, just below the aortic valve on the ventricular side, there is some thickening and fatty (?) degeneration, apparently the result of some past inflammatory condition. The mitral valve itself appears to be slightly contracted, and on the side of the ventricular wall divided by two indentations, also indicating mischief at some very *remote period. The ring at* the base of the valve is irregular, but I do not think there has been either obstruction or incompetence in any marked degree, though the thickening of the ring and the imperfect closure may have allowed of some reflux and of the formation of fluid veins as the blood passed directly through. The marked stenosis has led to very great hypertrophy of the wall of the left ventricle, but the muscle appears to be sound, though at points where the musculi papillares join the chordæ tendineæ, and from some distance down into the muscle there is an *increase of fibrous tissue.* This, however, is not an important feature. There is little or no dilatation. In the hypertrophied muscle there appears to be an increase in the amount of fibrillar tissue; this, of course, being much more marked near the endocardium where the endocarditis is a prominent feature.
>
> The external cusp of the tricuspid valve appears to be similarly irregularly divided, slightly thickened and retracted, and is very interesting. The pulmonary valves are normal. There was no abnormal communication between the chambers.

Remarks.

While coarctation of the aorta—i.e., the constriction of the descending arch—at a point between the left subclavian and the insertion of ductus arteriosus, though among the rarer of congenital abnormalities is yet not so very uncommon, a congenital stenosis at the level of the aortic valves is exceedingly rare; when it does occur it is usually due to the absence of one of the sigmoid valves and the exaggerated development taken on by the two others, the physical signs being those of an acquired aortic stenosis. The slight degree of impairment of general activity in view of the great contraction of the aortic orifice is, no doubt, partly explained by the great hypertrophy of the muscular tissue of the left ventricle, which was quite healthy, and the absence of any appreciable dilatation. This healthiness of the muscular tissue militates against the usual supposition that an inverted T-wave in Lead II. is indicative of myocardial degeneration. The pathological significance in this case of an inverted P in Lead III. I am unable to explain, apart from the fact that the auricular impulse must have arisen at an abnormal focus.

Montagu square, W.

OBSTRUCTION DUE TO THE FORMATION OF A SPUR AFTER FINNEY'S OPERATION.

By R. P. Rowlands, M.S. Lond., F.R.C.S. Eng.,
SURGEON TO GUY'S HOSPITAL

It may be remembered that in Finney's method of gastro-duodenostomy the pylorus, the pyloric end of the stomach, and the first part of the duodenum are, if necessary, thoroughly freed from adhesions, and the contiguous borders of the stomach and duodenum are incised downwards from the strictured pylorus for 2½ to 3 in. In this way the pyloric opening is greatly and permanently enlarged and pyloric spasm is prevented. (See Fig. 1.)

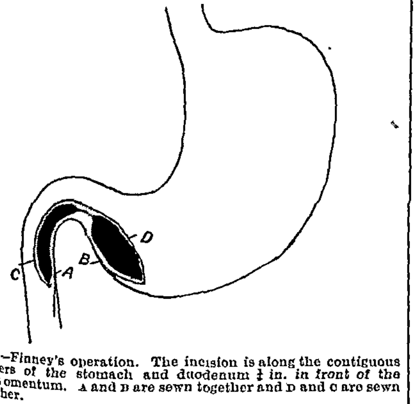

Fig 1.—Finney's operation. The incision is along the contiguous borders of the stomach and duodenum ¾ in. in front of the great omentum. A and B are sewn together and D and C are sewn together.

The following case, in which Finney's operation for gastro-duodenostomy had been performed, is, as far as the writer knows, unique. A spur formed below the anastomosis and almost completely hindered the exit of food from the stomach, with the result that the patient became so extremely thin that malignant disease was feared. An operation was only undertaken as a forlorn hope. Gastro-jejunostomy completely relieved the patient, who has since then ceased vomiting and has gained much weight.

L. J., a married woman, aged 40. Neurotic and thin. Had suffered for several years from indigestion, vomiting, and hæmatemesis. A diagnosis of gastric ulcer was made and she was admitted to Guy's Hospital for operation two years ago. A chronically inflamed appendix was removed and a dilated prolapsed stomach, with an ulcer on the lesser curvature 3 in. from the pylorus, was found. The pylorus and duodenum were movable and healthy, and as the stomach was much dilated and the patient of the neurotic type pylorospasm due to the gastric ulcer was thought to be an important element, and Finney's operation was chosen instead of gastro-jejunostomy. This was easily performed, a 3½ in. opening being made. The patient did very well while in hospital and went home within three weeks. Unfortunately, her doctor died just then, and his partner being at the war no one supervised her after-treatment.

Before very long vomiting returned and gradually increased and the patient lost flesh during the next two years. She was readmitted to Guy's in February, 1920, extremely emaciated, weighing only 5 st., and was examined thoroughly by radiography and chemical analysis of the gastric juice. Both these examinations were unsatisfactory because the patient vomited almost immediately after swallowing anything. The gastric shadow was small and distorted, and there was marked achylia. It was therefore suggested that she had a gastric carcinoma high up. Cardiospasm or other obstruction of the œsophagus was, however, definitely excluded by the X ray examination. As a last resort I explored the abdomen and was surprised to find a greatly dilated hypertrophied stomach; the ulcer had quite healed, leaving no trace beyond a small scar. The pyloric end of the stomach was greatly dilated and rounded off, the first part of the duodenum having become part of it. (See Fig. 2.) It was then recognised that there was a valvular obstruction between the stomach and the duodenum, and a posterior gastro-jejunostomy was rapidly performed. The patient went out of hospital eating almost full diet, putting on weight and gaining strength, and four months later I heard that she was doing well.

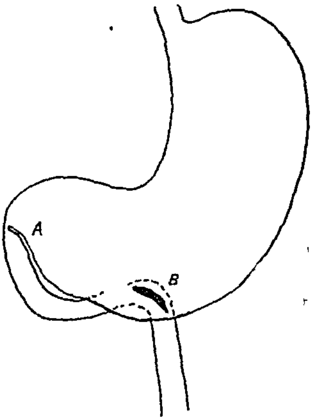

Fig. 2.—Spur formation after Finney's operation. A, Spur. B, Opening made at secondary gastro-duodenostomy.

The Advantages and Disadvantages of the Operation.

It is claimed that Finney's operation is easy and simple, and can be performed in a very short time. This is a distinct advantage when pyloric stenosis coexists with hour-glass contraction, and has to be treated after gastro-gastrostomy in a feeble patient. It is also claimed that the size and position of the new orifice are such as to provide free drainage of the stomach, unless the latter is greatly dilated and atonic; that spur formation and the development of a vicious circle are impossible, and that there is a special freedom from post-operative nausea and vomiting. The operation is thus peculiarly valuable for nervous women (regurgitation of bile does occur in some cases, however); even a large ulcer may be removed from the anterior aspect of the pylorus, stomach, or duodenum without fear of subsequent cicatricial contraction. There is no risk of jejunal ulceration after this operation. It does not interfere with digestion in the duodenum or with the reflex secretion of bile and pancreatic juice; hence absorption should be a little better than after short-circuiting.

Disadvantages.—Although the operation is a great improvement on pyloroplasty, the separation of adhesions is troublesome and may be dangerous. The after-results are not quite so good as those of gastro-jejunostomy. It is contra-indicated in most cases of active ulceration or with dense adhesions, and its mortality is higher than that of gastro-jejunostomy. The mesogastrium may be too short or the duodenum may be too fixed to allow easy approximation of the parts, which may then have to be joined in the depth of the wound. To these disadvantages the slight risk of spur formation must be added. This complication would seem more likely to happen with a greatly dilated prolapsed stomach and freely movable second part of the duodenum. A large opening, extending well down the gastric pouch, would diminish the risk.

Queen Anne-street, W.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OPHTHALMOLOGY.

EXHIBITION OF CASES AND SPECIMENS.

A CLINICAL meeting of this section of the Royal Society of Medicine was held on June 9th, Mr. **W. T. HOLMES SPICER**, the President, being in the chair.

Perithelioma of the Lid (?)

Mr. **R. S. CHARSLEY** showed a specimen of what he regarded as Perithelioma of the Lid. The tumour had been mistaken for an ordinary meibomian cyst by the practitioner and incised by him. When the case was referred to the exhibitor he removed the tumour, and the man remained in good health for two months. At the end of that period, however, the temporal bone began to enlarge, and the patient became less vigorous. Two months later still he developed weakness in the spine, and ultimately curvature there, probably due to a recurrence in the vertebræ. Death took place six months after the tumour became prominent. A pathologist pronounced it to be perithelioma. Mr. Charsley found the tumour at the operation was encapsuled, was easy to remove, and there had been no recurrence in situ when the man died.—Mr. **TREACHER COLLINS** regarded the growth as an alveolar sarcoma.—Mr. **M. S. MAYOU** alluded to the large size of the cells in the tumour, and inclined to the view that it was perithelioma. He had seen such tumours break down into soft caseous masses.

Mr. **LESLIE PATON** related the particulars of a case of Endothelioma of the Orbit, which he removed, completely in his own and others' view, but there was a progressive spread subsequently to the various glands of the body, the death two years after the appearance of the original growth having been directly due to a large mediastinal growth of the same nature.

Neuro-fibromatosis.

Mr. **A. W. ORMOND** showed a case of Neuro-fibromatosis (von Recklinghausen's disease). There was extensive pigmentation over the body, especially on the parts usually coloured, and there were many soft tumours, which felt like fibro-lipomata. The man was 28 years of age, a gardener, and his complaint on coming to the hospital was of headache and failure of sight. The vision was 6/18 in each eye, and there was optic atrophy as a sequel of papillœdema. Wassermann reaction was negative. The patient's hands and feet were larger than normal, and the supra-orbital ridges were very prominent; there was also some kyphosis. The tumours were not tender on manipulation. The systolic blood pressure was 105 mm., the diastolic 80. He thought the association of conditions pointed to over-action of the pituitary body, not unlikely to be due to a condition affecting the fibrous tissue at the base of the brain. Alexis Thomson had shown that in the recorded cases practically all the cranial nerves, in one or other of them, had been involved. Mr. Ormond exhibited skiagrams of the skull.—Mr. **J. H. FISHER** thought that probably there had been an irritation of the pituitary body, causing the hypersecretion which eventuated in the acromegaly.

Cyst of the Iris.

Mr. **W. H. MCMULLEN** exhibited a patient with Cyst of the Iris. It had been dealt with by iridectomy, part of the cyst being removed. There was no history in this case of injury with resulting implantation of epithelium, the usual course of events in these cases. The condition was noticed when the child was less than a year old, hence it was either congenital or had developed at a very early age. As the tension of the eye was normal and the condition appeared to cause no inconvenience, he proposed to leave it alone.—Mr. **FISHER** related a similar case, and thought there had probably been an accidental puncture which had not been noticed and which quickly healed up.—Mr. **TREACHER COLLINS** pointed out that cysts of the iris did sometimes arise without there having been a puncture injury. Endothelial cysts could be cured by transfixion, and he related a case in point.—Sir **WILLIAM LISTER** thought the careless habit of some women of putting pins and needles in pillows and cushions might be answerable for some of these cases; the baby might be put on to such a pillow and nothing wrong be noticed, as there would probably be rapid healing.—Mr. **ORMOND** supported Sir William Lister's view, and spoke of three or four cases he had had fairly recently in which the parents had no idea of how the condition was caused.

Other Cases Shown.

The **PRESIDENT** exhibited a patient who had Horse-shoe-shaped Opacities in the Cornea. The only complaint was a gradually diminishing vision during the last few years. No other member of the family had a similar condition. The history obtainable was purely negative.

Mr. **G. W. ROLL** showed a child, aged 3 years, the subject of Herpes Ophthalmicus. The attack occurred in February last, simultaneously with chicken-pox, the eruption remaining on the brow. Part of the eruption was along the nasal nerve to the tip of the nose, and the cornea also was involved. The intimate connexion between chicken-pox and herpes ophthalmicus had been noted by many observers. He referred to other cases of the condition.

The **PRESIDENT** and Mr. **FISHER** related similar cases.

Mr. **J. F. CUNNINGHAM** brought forward a case in which a mass obscured the optic disc. The school medical officer discovered the defective vision, and the father brought the boy to the ophthalmic hospital, where a history of trauma was elicited.

Dr. **RAYNER BATTEN** showed a case of Superficial Punctate Keratitis, which had persisted two years and proved very resistant to a great variety of treatments.

The **PRESIDENT** mentioned a similar case in his own practice, in which the treatment seemed equally hopeless. In that case the disease, after a number of years, appeared to wear itself out.

Mr. **MCMULLEN** showed a second case, one of Congenital Malformation in the Outer Canthus, an appearance unique in his experience and in that of others whom he had shown the patient to. The outer extremities of the left lids were separated by a low pad or cushion of tissue covered with skin. The suggestion of an amniotic band and adhesion before the displacement which had been made seemed a likely one.—Mr. **TREACHER COLLINS** said the case reminded him of the class of case described by Sir George Berry, of which the speaker had himself had examples, in whom there was a remarkable symmetrical flattening of the malar bones, causing him at first to suspect that the patients were brothers. He thought the condition was best explained on the hypothesis of some delayed closure of the cleft between the fronto-nasal plate and the superior maxillary plate at the outer canthus.

Mr. **M. L. HINE** showed a case in which a sebaceous horn had become malignant, had recurred after removal, and was very greatly improved by a single eight-hour application of radium. The case was still under treatment and observation.

The concluding exhibits were a case of Furrow Keratitis by Mr. **P. G. DOYNE** and a specimen of "Daylight Glass" by Mr. **W. WALLACE**, such as had been evolved from the investigations in Cornell University, U.S.A. It was very largely employed in that country for microscope work, and was also used in many large factories.

NORWICH MEDICO-CHIRURGICAL SOCIETY.

EXHIBITION OF CASES AND SPECIMENS.

A CLINICAL meeting of this society was held at the Norfolk and Norwich Hospital on June 1st, when a number of interesting and unusual cases were shown.

Dr. **H. MUIR EVANS** (Lowestoft) exhibited two specimens of Uterine Myomata with Complications, and Sir **HAMILTON BALLANCE** exhibited the following specimens (1) prostate removed entire from a man of 76, showing a well marked middle lobe, (2) large papilloma growing from the anterior wall of the bladder, removed from a man of 65, (3) pylorus and adjacent parts of stomach and duodenum, showing a malignant growth, removed from a woman of 50

Sir H BALLANCE also showed the following cases —

1 Boy aged 6 with severe double congenital talipes equino varus The left foot had been operated on—the astragalus navicular cuboid and some of the anterior part of the os calcis had been removed There was still some displacement inwards of the anterior half of the foot to be corrected

2 Man aged 34 Gunshot wound of the left arm four and a half years previously causing complete and permanent paralysis of the musculo-spiral nerve with wrist drop The palmaris longus tendon was divided and sutured to the long extensor of the thumb the flexor carpi radialis to the common extensor of the fingers and the flexor carpi ulnaris to the extensor carpi ulnaris

3 Man aged 29 Wounded five years ago in left chest and abdomen portions of the seventh and eighth ribs being carried away Four years ago silver wire filigree 4½ in by 3 in was inserted to cure a hernia where the ribs were missing At the present time the patient has great discomfort from a large hernia of the stomach through the diaphragm into the left side of the chest which it is proposed to operate upon The heart is displaced to the right Two skiagrams taken with bismuth in the stomach were shown one with the patient standing up and the other when he is lying down The wire filigree appeared in position

Mr G MAXTED showed a very interesting case of Congenital Coloboma of the Disc, which had been at first diagnosed as a case of glaucoma

Mr A J BLAXLAND showed a case of Excision of the Rectum, with preservation of the external sphincter He also showed a case of Sprengel s Shoulder (congenital elevation of the scapula), though some of the members did not agree as to the diagnosis

Dr MUIR EVANS exhibited a case of Renal Dwarfism in a girl of 17, in which the prominent symptoms were arrested growth, difficulty in walking, marked genu valgum, enlargement of the ends of the ribs, combined with a urine of low specific gravity (1005) containing a considerable amount of albumin, and a low blood pressure (80) He referred to several cases of renal disease associated with bone changes which had been described by Dr Hugh Barber, of Derby, in a paper published in THE LANCET last January

Dr H J STARLING brought forward a case of the rare condition known as

Coarctation of the Aorta

The patient was a pensioner aged 40 who had been before the war a railway labourer doing heavy work. He enlisted in June 1915 and was sent to Mesopotamia in January 1916 when he began to have dyspnœa and was transferred to a hospital in India for V D H thence to Alexandria where the case was diagnosed as aortic aneurysm He was sent to England and discharged in August 1916 for V D H and orchitis and has done no work since Present symptoms are pain round the precordium and dyspnœa on exertion Pulse rate is 76 after 40 hops 100 after one minute 80 X rays show no evidence of aneurysm The apex beat is heaving in the fifth space just outside the nipple line A blowing systolic murmur can be heard at the apex in all postures and the aortic second sound is accentuated The subclavian radial and carotid arteries are hard full and heaving The blood pressure in the brachial artery is 255–148 The abdominal aorta and the femoral and popliteal arteries are difficult to detect and the blood pressure in this system is too low to be estimated accurately There is a mass of varicose arteries in each axilla and tortuous arteries can be seen or felt under the skin in the areas supplied by the intercostal mammary epigastric and other arteries The course of the blood is from above downwards

Dr Starling said that this condition was due to a partial or complete obliteration of the aorta just below the left subclavian artery 142 cases had been recorded, 9 in infants and 133 in adults, 92 being males and 41 females the majority had died between 20 and 40 years of age, but one case lived to the age of 92

Pellagra

Dr G A GOLDEN, assistant medical officer, Norfolk County Asylum, showed a case of Pellagra in a female patient the subject of chronic mania with dementia The characteristic sun burnt appearance of the backs of the hands and wrists was well marked, and there was a pustular eruption round the mouth, though the rash was not so marked as it had been the day before Dr Golden could not account for the causation of the disease in this case, but referred to some similar cases which had occurred at Napsbury Asylum, and were recorded by the late Dr G S Blandy in THE LANCET of Sept 6th, 1913 Dr Golden said that pellagra was practically unknown in England, except for its occasional occurrence in asylums

Reviews and Notices of Books.

TRAITE DE L'IMMUNITE DANS LES MALADIES INFECTIEUSES

By JULES BORDET Paris Masson et Cie 1919 Pp 720 Fr 40

IT is nearly 20 years since the appearance of Metchnikoff s "Immunity, ' and among the various later volumes on the subject which have been published none has covered the ground in quite the same broad way The accumulation of details on the basis of the generalisations of Metchnikoff and Ehrlich has been tremendous, good, bad, and indifferent data have been heaped on top of one another into chaotic piles many earnest immunologues have been too busy doing Wassermann's test in an improved way, or quarrelling about anaphylaxis to try to make out what it all means, it has been easier to give a dose of vaccine or to invent a fresh penny in the slot diagnostic test The inspiration of the fundamental theorems of the "nineties" has been dying away, and in the absence of any general ideas to replace them serology has drifted into what bears a tolerable likeness to a blind alley It is plainly time to take a serious survey of the position and Bordet s sane, sensible discussion of the facts and fancies of immunity is not the least of the many conspicuous services he has rendered to the study of infection He provides a well balanced review of immunity as a wide biological problem rather than as a by path of medicine Like many good books, it asks more questions than it answers and carries with it that placid stimulation which is the comfort of the scholarly products of learned men

The author has been in the thick of the subject from the beginning, and he weaves together the old facts and the very real progress of recent years into a tale so coherent that his readers will feel that the ground is strong enough to carry the fresh investigations which his pleasant narrative will stimulate them to undertake Of course, the whole of "immunity is not in the book anyone who wants to will probably find the section on his own pet topic defective No one could make a place for all the trees, real and sham, in his picture of this particular wood But the picture as a whole, is a very good one, and the new committee on biological drugs might well set it as a compulsory text for manufacturers of sera and vaccines

There are some dreadful omissions—no index and no references to literature and the table of contents is quite inadequate The author remarks in the preface that a bibliography would have been too much trouble, and recommends those who want further details to hunt up the names (which he quotes mostly with dates) in the *Bulletin* or *Centralblatt* It is exasperating that no one finished off the book properly when the author got bored, for these mechanical defects greatly damage its use for reference

---

MANUAL OF VENEREAL DISEASES FOR STUDENTS

By Colonel L W HARRISON, D S O, M B, Ch B London Henry Frowde and Hodder and Stoughton 1920 Pp 360 27*s* 6*d*

THE author has produced an excellent text book for students A "Manual of Venereal Diseases for Students bears a very great resemblance to the "Diagnosis and Treatment of Venereal Diseases in General Practice, a work that has had an extremely favourable reception from the profession We confidently anticipate that the Manual for Students will be as favourably received Little has been lost in the process of condensation Some useful chapters have been added A brief description is given in Chapter IV of the technique of urethroscopy and of the common lesions seen during such an examination The importance of instituting the most stringent tests of cure in the case of gonorrhœa has been rightly emphasised Chapter V is devoted to the difficult subject of gonorrhœa in women, a side of venereal disease that was formerly neglected in many text books but the supreme importance of which is now universally recognised. The author is cautious and non-committal when dealing with the subject, and Chapter XXVI. is perhaps less convincing to the reader than any other portion of the book. However, the subject is admittedly a difficult one, and one on which it is impossible yet to write with any certainty—much clinical experience remains here to be recorded before dogma becomes possible. Four useful appendices have been added to the book. The first of these gives a sketch of the principles underlying complement-fixation tests, and the second a description of common stains used in the detection of micro-organisms. The third and fourth appendices furnish formulæ for use in the treatment of gonorrhœa and of syphilis respectively. Additional coloured plates and illustrations appear in the new Manual and contribute considerably to its interest.

Although written primarily for the student, the Manual of Venereal Diseases will appeal with equal force to the general practitioner. It is eminently a practical work, and the amount of information it contains within its 360 pages is prodigious. When the small amount of knowledge of venereal diseases that has been demanded of medical examinees in the past is considered, the quantity of information set before the student by Colonel Harrison appears at first sight somewhat overwhelming. However, as the author states in his preface, the importance in medicine of gonorrhœa and syphilis cannot be easily overestimated. In the past the student's knowledge of these diseases has been totally inadequate, and it is only within the last few years that this has been apparent. A text-book of the quality of Colonel Harrison's Manual of Venereal Diseases should do much to repair this omission. The work should receive favour from student and qualified practitioner alike.

MODERN ANÆSTHETICS.

Second edition. By J. F. W. SILK, M.D. London: Edward Arnold. 1920. Pp. 191.

THIS little book remains an eminently pleasant one from which the student can learn the elements of the theory and practice of anæsthetics. The second edition has been kept to about the size of the first, although the latest developments are duly recorded. Dr. Silk had the advantage of acting as consulting anæsthetist during the war, which gave him an unusually wide view of the practice of other men, and he has not failed to utilise the experience. His own preference, if he were asked for a routine anæsthetic, appears to be for open ether with 3 per cent. chloroform, and he is fond of the Rendle's inhaler. We think he dismisses the management of abdominal cases a little cursorily, and that he might with advantage have added a paragraph on anæsthetics in labour.

DOMUS DOLORIS.

By W. COMPTON LEITH. London and New York: John Lane. 1919. Pp. 222. 7*s.* 6*d.*

Hooker, the great English seventeenth-century divine, once wrote a panegyric on the Psalms which he had adapted from an exposition of Torquemada the Dominican, and part of it ran thus:—

> "Heroical magnanimity, exquisite justice, grave moderation exact wisdom, patience unfeigned, unwearied patience, ... all good necessary to be known or done or had, this one celestial fountain yieldeth. Let there be any grief or disease ...... any wound or sickness named, for which there is not in this treasure house a present comfortable remedy at all times ready to be found."

This passage always seems to us as applicable to the treatment of sickness and wounds as to the treatment of souls, and we think it more than probable that Mr. Compton Leith had it in mind when he wrote the very charming essay on a hospital which is now before us, and that all the more as his writing is saturated with seventeenth-century rhythms. His is a striking book, and any reader who has worked in a hospital will feel even more proud of having done so than he did before. Anyone, moreover —and there are all too many to-day—who has been a tient should feel grateful to Mr. Leith for having out in noble words the feelings which he should but may be unable to express. The praises of the staff, the consciousness that all who work in a hospital are members of a great fellowship, the parallel drawn between a hospital and a university, are finely imagined, and Mr. Leith's prose has exactly caught the elusive character of thoughts during sickness and convalescence—the reader is carried on as in a dream. Anyone who knows his classics will revel in the happy allusions to, and quotations from, the great writers of Greece and Rome, of which there are many—e.g., we have noted Homer, Thucydides, Æschylus, Aristophanes, Theocritus, Lucretius, Virgil, Juvenal, and the practically unknown Sulpitia, whom Mr. Leith is good enough to mention by name, fearing, we presume, and rightly so, that otherwise but few of his readers would know to whom he was referring. The medical profession owes a debt of gratitude to Mr. Leith for this "epaenetic"—to use one of his own words—of our calling.

THE BRITISH SYSTEM OF PHYSICAL EDUCATION.

By BEATRICE E. BEAR, M.B.A.P.T., Co-Principal of the Queen Alexandra's House Physical Training College. London: G. Bell and Sons, Ltd. 1920. Illustrated. Pp. 128. 8*s.* 6*d.* net.

THIS book is, we presume, intended to serve as a class-book in the college of which the author is co-principal. For students elsewhere it is inadequate; for teachers it contains little that will help them. In the preface the Swedish system is described as the grammar, and the British as the literature, of physical education. The text either pre-supposes a knowledge of the "grammar" or ignores its importance. Thus we read that games and sports are held to be necessary for all-round development, and yet no further reference is made to them. In the Swedish system, as we know it, dancing and games form an integral part of training, despite the fact that Sir James Crichton-Browne, in his introduction, stigmatises this system as "a drill." The author devotes much space to marching, but if this is supposed to replace the dancing of the Swedish system we frankly prefer the latter. To those unfamiliar with the technicalities of physical training and education a perusal of this book may be impeded by unfamiliarity with the abbreviations freely used. The method of illustration is good, though Figs. 17, 45, and 51 (apparently made from the same block) depict an almost impossible exaggeration of position.

SAPPHIRE WINGS.

By Surgeon-Major COOK, 1st C.B. Roy. Fus. London: J. Hewetson and Son. 1920. Pp. 68. 2*s.* 6*d.*

Surgeon-Major Cook has several volumes of verse to his credit, and we see no reason why this one should be the last, for his muse is not exacting. There is nothing very distinguished in thought or expression in the volume before us, but the author exhibits a technical facility which many bards might envy, and a definite point of view which many lack. We ourselves should have to be up very betimes to rhyme reason, puttees on, policeman, and squeeze on, with diocesan; and it is remarkable that this feat should have been accomplished, as we are assured it was, in hours snatched from slumber after a hard day's work. The two dozen poems in this collection touch on a variety of subjects from Heaven to the Royal Academy, and there is tough scientific stuff as well.

"Deaths by disease were, erstwhile, six to one
  Of wounds that slay,
Disease now claims but one, to sixteen slain—
  A better way;
Nine out of ten given back, if six hours run
  Ere death has sway;
And those for whom Field Hospital is won—
  Ninety and five see day!
Now, of each hundred wounded, at the Base,
  Full ninety-eight
Reach home. . . . . ."

This is ingenious, even though pedantry may prefer the form in which the Registrar-General presents his statistics. The following line contains a heresy—

"Knew the canker that lay burning at the root."

The best cankers never burn; they gnaw.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

—o—

THURSDAY, JUNE 3RD.

AT a meeting of the Council on this date SIR JAMES HODSDON, the Chairman of the Committee, submitted the

Report of Dental Education and Examination Committee,

which set out the returns of the professional examinations in 1919 and of exemptions granted by the dental authorities.

The PRESIDENT remarked that the tendency was increasing throughout all the Dominions to restrict the practice of dentistry to duly registered people, hence the mother country was being surrounded by a ring of self governing Dominions which in this matter were in advance of her.

The report was agreed to

Teaching of the Preventive Aspects of Medicine
A Significant Report.

DR. MACKAY (chairman of the Education Committee) presented a Further Report by the Committee,[1] which was made the occasion of an exhaustive discussion. The Report ran in substance as follows —

The Committee first draw attention to a Memorandum by Sir George Newman, entitled "Some Notes on Medical Education in England' [2], to "An Inquiry into the Medical Curriculum, published by the Edinburgh Pathological Club [3] and to the resolutions (1916)[4] and recommendations (1909) which have been issued by the Council to teaching and qualifying bodies After allusion to the fact that the term "Preventive Medicine" in the Circular Letter referred to the *general education of the student in medicine*, and not to special instruction in hygiene, it is pointed out that the Letter has had in view what may be called the pre morbid state and the necessity devolving upon the practitioner of taking measure to eliminate influences affecting individuals professionally under his care which threaten to produce disease The replies to the Letter received by the Committee indicate by their general tenor that present day training does not concern itself sufficiently with the preparation of the student for the discharge of these important *elements of the practitioner s duty*

The particular points raised concern primarily that *portion of* the teaching work which belongs to what is here called the clinical group of teachers, those who directly train the student for the practice of his profession, but as the earlier courses of study form together a graduated scheme of instruction designed to prepare the student to receive the actual training in his life work, which he can only *obtain* at the hands of his clinical teachers, it is clear that the whole *curriculum necessarily comes under review*

Since, under the *particular aspect of* "*Preventive* Medicine ' to which attention has been called, the recognition of pre morbid and early morbid conditions is essential, an accurate knowledge of the limits of normality in structure, function, and reaction in the human body is specially called for This involves the special consideration of the teaching in anatomy, physiology, and pharmacology, and on the other side of the boundary line, of pathology also It is proposed to call the attention of the Council in the first place to *certain general considerations* which affect the question as a whole, and afterwards to deal very briefly with the particular aspect of the problem as it presents itself to each of the several departments A full and open discussion will pave the way to ultimate solution The ideal curriculum cannot yet be established students begin too early, teachers are over burdened, clinical instruction is often carried out under adverse conditions

The particular aspect of medical training to which, under the name of ' Preventive Medicine,' *the attention of the schools* has been called represents the *first stage of a coördinated system* The reply sent by the University of Oxford to the questionnaire may be quoted in this connexion "It is accepted that, generally speaking, either from the clinical or from the pathological standpoint, disease is more easily recognised in its later stages As the student has to be taught the easier problems first, it follows to a certain extent in *practical* instruction disease must be taught in the reverse order of its development '

The consideration of the length of the curriculum would naturally be taken up in ordinary circumstances at the close of the discussion, but it is to be noted that none of the bodies which have sent in replies have proposed that the teaching period should be extended, although many speak of an overloaded curriculum It is impossible to avoid some overlapping in discussion and it will be found *convenient to take*, in the *first place, the distribution of the* work of training among the different classes of teachers and the allocation of each particular branch to its appropriate place in the curriculum The clinical teachers, the sole instructors of the *student in all that concerns the actual practice of the profession*, are naturally *deeply versed in the earlier* sciences, but they practise a science *of their own*, and *medicine is infinitely more* than a mere combination of these The principles of physiology, pharmacology, and pathology are united in one system working in an environment in which material, vital, and spiritual influences are blended, and having its own laws and its own evolutionary history Until recently the clinical teachers undertook the whole work of medical training but the vast increase of breadth and the multiplication of details in every department of medical study have *compelled specialism* It *lies with the staff* in medicine, surgery, and *midwifery, and in all the minor branches of these departments* to deal with the *whole training of the student* The ancillary subjects cannot be exalted by their teachers without impairing coordination of the whole when either the student or the teacher undertakes work for which he is not qualified Sir George Newman's Memorandum points out, talking of the clinical aspects of anatomy, that the principal anatomical lessons should be introduced by the clinical teachers 'as an integral part of the clinical aspect, and in dealing with the teaching of obstetrics and gynæcology he takes a similar view

The importance *of the question of the proper coordination of* studies has been specially emphasised in many of the replies A full discussion of the subject is contained in the report from Guy s Hospital Medical School and many interesting suggestions are proposed therein The Edinburgh Pathological Club also deals exhaustively with the subject, and puts forward a detailed scheme embodying their proposals for the distribution of the several studies throughout the curriculum One of their suggestions, to *the effect that the student should begin his clinical instruction in his first year, will probably not prove acceptable to the majority of* teachers The work of the clinical instructors is already very severe, and the overcrowding of clinical classes with students wholly untrained, having no knowledge either of bodily structure or bodily function, would not tend to lessen it The necessity for coördination of studies is convincingly stated by Sir George Newman "There must be reasoned effort to eliminate the unnecessary and the redundant, and to concentrate on the essential things ' ' We *may* well *reduce the data of botany and chemistry and* begin with the *preliminary* sciences earlier we may strip the study of anatomy and physiology of useless memorising of unimportant detail we may abolish a considerable amount of materia medica and some pharmaceutical work, we may diminish the number of systematic lectures in almost all directions and we may bring tutorials and our examination system into subjection The consideration of the Council is invited to the general principles on which *coördination of studies should be based*

The *ideal scientific method in training* cannot be realised in entirety in medicine because of the circumstances in which the teachers must of necessity work Subjects cannot be taught as progressive sciences in themselves when they are ancillary to something else The vast increase in recent years of medical knowledge, the bringing to light of new facts, have augmented the difficulties of the teacher, and now there is grave danger that the scientific spirit and scientific methods *of instruction may be forgotten, and that medical education may degenerate into an elaborate* and laborious system of memorising The danger is imminent, it seriously affects the future of medical research in this country Some of the difficulties are unavoidable, others may be met The more serious may be overcome if it be generally agreed that from the teachers in the earlier sciences (the term is used to include all except the clinical subjects) no more is to be expected than that they should impart to their students an intelligent and scientific appreciation *of the subjects which they profess* Doubtless they *should*, but always *in pursuit of their* primary objects make use, *as far as* possible, of material likely to be of subsequent clinical interest to the student, and employ such clinical knowledge as they possess in illustrating and emphasising the importance of particular branches of their work, but their real teaching should be confined to their own special spheres

In a report made to the Council *in 1890* the *Education Committee*, discussing *the length of the curriculum* and advocating its *extension to five years* made the following statement concerning the methods of examination "The Committee would further remark in view of the potent influence of methods of examination in determining methods of education that it would tend greatly to induce more attention to practical work were the practical part of the examination in all the subjects *extended and less time occupied* with the written examination ' *This piece of advice seems to have been lost sight of, perhaps because it did not go far enough* Preparation *for the* written examination compels the student to text book work Knowing that his success will largely depend on the completeness of his answer he expends much time and effort in memorising many details, of the relative importance of which he cannot judge, since his text book seeks to *give all* without discrimination The text book is a danger to the *student it tends to* destroy his own *initiative and judgment* The preparation for oral and *practical* examinations demands the seeing and handling the subject and discussion with teachers, and so promotes the student s understanding and corrects his reading The Council might well re-open the discussion of 1890 and consider the methods of examination

The aims of the present Inquiry are primarily *concerned* with clinical work, and to extend and *improve the opportunities* for clinical study *These may be realised by an extension* of the clinical period, *adding to it at either end* The former plan would lengthen the curriculum, the latter would require the introduction of blocks to prevent the encroachment upon the clinical time Clinical teachers have complained of these encroachments already The precise question may therefore be stated—Can the teaching of the *subjects* preparatory to clinical study be made *lighter* and less exacting on the student and, at the *same time*, be better adapted to his future *needs?* Otherwise there must be extension of the time-period of the whole curriculum, the addition to be exclusively devoted to clinical work, but consideration must be given to the needs and conditions of each of the earlier subjects and an extensive readjustment made of teaching methods and arrangements *If some* measure of agreement should be reached on the general questions raised in the Report, the necessary investigation may be to some extent simplified. Some detailed suggestions are put forward for discussion.

---

[1] An Interim Report by the Education Committee *on this subject* was presented to the Council *on* Nov 26th, 1919 It is printed in extenso in the minutes of the Council for 1919 (pp 347-393) The Interim Report contains in an appendix a number of replies to the Circular Letter on the subject addressed by the Council to the teaching bodies Additional replies received since the November Session of the Council are embodied in the appendix to the present Report The letter was addressed to 38 *bodies in all*, replies have now been received *from 30 of these*

[2] THE LANCET, August 3rd, 1918, p 147

[3] THE LANCET, Jan 26th, 1918, p 147

[4] THE LANCET, Dec 9th, 1916, p 988

Preliminary Education in General Knowledge.—Much advantage would be gained were the minimum age at entrance raised to 18. The last two years of school life might be largely devoted to chemistry and physics, and a pass-certificate in these subjects of the higher standard might be accepted for some portion of the work in inorganic chemistry and general physics in the schools of medicine. This would naturally lessen the pressure in the first year of the curriculum and increase the time available for the study of anatomy and physiology. If the change be made it must be universally applicable. The teaching in all the earlier subjects is carried on and amplified by the teachers in all the later subjects, each employing some portion of the organised knowledge which the student has gained and amplifying it for his own special ends. The curriculum cannot be divided into separate compartments. All the teachers, for instance, who follow the biologist are adding to the students' knowledge of biology something which the biologist cannot himself give them. It is the duty of the later teachers to carry on the teaching of all the sciences which precede their own sciences in the curriculum. The courses in the preliminary sciences must of necessity be general in their nature. At the same time, wherever possible, the earlier teacher in selecting his material should make use of all which, without detriment to his special purpose, is likely to arouse the interest of the student in the practical applications of the subject throughout his later work.

Biology.—Applied biology should be taught later to the student in the classes of anatomy, physiology, pathology, bacteriology, public health, and medicine. There is not much divergence of opinion among the replies as regards the teaching of this subject and the preliminary sciences generally.

Chemistry.—Inorganic chemistry, if taught in schools for two years to pupils above 16 years of age and certified by a pass-certificate of the higher standard, as has been suggested above, might with advantage replace the elementary course usually given in the schools of medicine. Organic chemistry, on the other hand, should probably, for the present at least, be retained in the curriculum; its study demands a closer application than the average school-boy is accustomed to give. The subject is taught in applied form in physiology, pathology, pharmacology, medicine, and public health.

Physics.—The subject should include the elementary mechanics of solids and fluids, and the rudiments of heat, sound, light, and electricity. There is usually allotted to it in the curriculum a period of three months' study (lectures and practical). The subject forms an essential basis for every branch of medical study. The teacher naturally cannot specialise in physical therapeutics, radiology, and electrical treatment as is suggested in the Circular Letter; he has barely time to deal adequately with the most general principles of his science. If physics were undertaken by the schools under conditions similar to those which have been mentioned in connexion with inorganic chemistry, there would not only be some slight ving in time, but a vast improvement in teaching.

Anatomy.—The subjects of anatomy and physiology of necessity overlap, but while recognising this, it is of advantage to treat them separately in the present inquiry, as their teaching methods differ widely in practice. No subject in the whole curriculum is so overburdened with detail as is anatomy, and its study and examinations constitute on this account a danger to the student. The reasons for this are sufficiently obvious. The teaching of embryology in the medical schools is of comparatively recent date; even in the near past teachers of anatomy have frequently been surgeons, and have naturally taught the subject, to a large extent, from the point of view of its clinical applications; from the observance of this custom medical teaching has not yet been entirely emancipated; the subject itself demands the memorising of many details not yet explainable under scientific principles. Anatomy should be taught as a science, an end in itself, not as a clinical study but as a preparation for clinical study. It should be based as far as possible on morphology and embryology, with constant reference to physiology, and should be illustrated as freely as possible by demonstrations from the field of pathology which immediately succeeds to it in the curriculum. As the teacher is called upon to give the student comprehension of the development and structure of every organ of the body, osteology must be dealt with in detail, as also arthrology, myology, the central nervous system, the lymphatic system, and the general distribution of peripheral vessels and nerves. Without continuous teaching in embryology few of the complications of his subject can be understood by the student. He should be taught the anatomy of the living body, embracing in this the normal bodily proportions, surface markings, the positions of the viscera, and the actions of the joints and muscles. This is the true interpretation of the term applied anatomy, which is used in two senses in the replies to the Circular Letter. On the other hand, the anatomist should avoid in his teaching all that would naturally fall into a course of surgical anatomy given by a surgeon in the clinical years of study, during the period when the student is concerned with clinical problems and in direct contact with clinical cases. The student may be spared in the ordinary anatomy class very much of the vast accumulation of minute details concerning the inter-relation and the fine distribution of vessels and nerves with which his text-books are loaded. The work of the dissecting-room, continued through a period of five terms, is intended to familiarise the student with bodily structure, to let him see and handle, but not to fit him for examination in minute details. It is a preparation for, but not a study of, surgical anatomy.

Physiology.—The teaching usually extends through three terms, and is carried out in a lecture course and in three practical classes dealing respectively with histology, animal experimental physiology, and chemical physiology. In view of the importance of the subject it cannot be said that too much time is given to physiology, or that anything is likely to be gained by reducing the period of study; but, on the other hand, a modification and a rearrangement of the work might indirectly be of assistance to the clinical teachers by lightening their labours, and would, at the same time, be likely to increase the practical value of the course to the student.

As has been suggested in discussing the teaching of anatomy, a practical course dealing with the employment of physiological methods in the study of the normal human being might with much advantage be instituted. This proposal is put forward and strongly pressed by Sir George Newman, who gives by way of example a specimen syllabus of the suggested course. It deals with the examination of the heart in action, blood pressure, and blood counting; with respiration and the determination of vital capacity; with the use of the clinical thermometer; with electric stimulation of muscles, muscle fatigue, and muscle reflexes; with the practical examination of sensory impressions from skin, muscles, labyrinth, and eye; and with the testing of the functional integrity of the various organs of the body. This may be named a course in applied physiology. To make room for the effective carrying out of a syllabus based on these or similar lines a considerable portion of the usual course in experimental animal physiology might advantageously be dispensed with. Oxford University has established, under the name of clinical physiology, a special course dealing with the physiology of man, in respect to the cerebrum, to dietary, to particular muscular acts, to some features of the human life-cycle, &c. Where this is not already done it might be well to follow the Oxford example. A number of replies to the Circular Letter approved the institution of courses of applied anatomy and physiology, as instituted at Middlesex Hospital.

Materia Medica, Pharmacy, Pharmacology, Therapeutics.—Sir George Newman considers that the two former might be largely dispensed with, that pharmacology should be taught in the laboratory as continuation of physiology, and might be limited to the study of the action of some 40 to 50 drugs, of the most important of which he gives a list. The instructor in therapeutics should be a clinical teacher well skilled in pharmacology, and the study of the subject should be carried on in the wards and out-patient departments. The teaching should deal not only with the effect of drugs, carefully watched from day to day, but with the influences of other remedial agencies, as dietetics, rest, hygiene, hydrotherapy, electric treatment, Finsen light, X rays, radiotherapy, remedial gymnastics, thermotherapy, climatology, open air, massage, and psychotherapy. The teacher should also pay special attention to the actions of vaccines, antitoxin serums, thyroid extract, and salvarsan.

Pathology and Bacteriology.—Many of the bodies have taken no notice of these subjects, but almost all which have dealt with them in their replies are in agreement that bacteriology is sufficiently taught. In pathology some admit deficiencies in the teaching, particularly as regards ætiology and the recognition for preventive purposes of the earliest indications of disease. Others in this connexion state that instruction in clinical pathology is given later in the curriculum. The exceeding difficulties of procuring autopsies in Ireland is noted from University College, Cork. Sir George Newman, pointing out that pathology, broadly speaking, is "Medicine, the Study of Disease," advocates the establishment of pathological institutes, properly staffed, in connexion with the teaching hospitals, and a remarkable memorandum from Guy's Hospital covers this and similar ground. The course outlined by Sir George Newman is virtually "clinical pathology," and deals with a most important aspect of the subject which has hitherto been largely neglected; it should be continued to the end of the curriculum, and should be examined on in the final or qualifying examination along with medicine, surgery, and midwifery. There should be, however, a precedent course on the general principles of pathology, which, however, might be materially reduced in length if clinical teaching were systematised. Comparative pathology might also be dealt with in the laboratory of the medical school or university.

Normal Psychology.—Fourteen bodies have given attention to the interrogation concerning this subject, and the majority hold that some instruction should be given by the lecturer in mental diseases as a prelude to his course. Few regard the subject as falling within the domain of physiology.

Public Health, Hygiene, Preventive Medicine.—On this subject, variously designated among the teaching bodies under the titles given above, no one can speak with greater authority than Sir George Newman, and the attention of all the schools is called to the chapter devoted to it in his Memorandum. After discussing the general aspects of the teaching, he gives in detail, in an addendum, a statement suggesting the scope of the teaching required by the ordinary student: "The following statement is intended to be suggestive of the nature of the preventive medicine which should form an integral part of the warp and woof of the medical curriculum. Certain sections should no doubt be incorporated in the course of hygiene for medical students; other sections should be included in the appropriate subjects of the curriculum, such as physiology, pathology, medicine, surgery, or obstetrics, which in greater or less degree is the case at the present time in some schools. The proposal is not to add a new subject, nor to lengthen the student's curriculum as a whole, nor even to inflate the subject of 'hygiene'; the essential point is that every medical student, before or after graduation, shall receive proper instruction in these matters (some of which are at present almost wholly ignored), and become imbued with the purpose, practice, and spirit of preventive medicine. He must understand the preventive aspect of medicine, surgery, and obstetrics. The statement, which has been advisedly kept simple and elementary, is designed for the medical student, and not for the student reading for a diploma in public health. A consideration of the daily needs of the medical practitioner in ordinary practice in England or Wales will, it is submitted, be found to justify the contents of the statement, the subjects of which should be illustrated and taught, as far as practicable, by means of demonstration or example."

The statement contains 24 sections, and specifies in detail the contents of each. The subdivisions may be omitted here, and the headings alone quoted: (1) meaning and scope of preventive medicine; (2) administrative machinery of preventive medicine; (3) maternity; (4) medical care of infancy; (5) the young child; (6) school hygiene; (7) personal hygiene of adolescent and adult; (8) the dwelling house; (9) the housing question; (10) food-supply; (11) milk-supply; (12) water-supply and the public health; (13) alcohol and alcoholism; (14) infection and infectious diseases;

(15) principles of epidemiology, (16) diseases of animals communicable to man, (17) the prevention of infective disease (18) vaccination and antitoxin inoculation, (19) prevention of other forms of disease, (20) vital statistics, (21) health insurance, (22) nuisances and dangerous trades, (23) industrial hygiene, (24) medico-sociological questions in relation to medical practice

The course will naturally fall into the final year of study At first sight it may appear to be unduly extensive, but a large proportion of its contents will already, in a properly coördinated curriculum, have engaged the attention of the student in other classes Thus it will serve a double purpose (1) the instruction of the student in the methods and results of recent work in public health and (2) the focussing of his knowledge, gained in many departments of study, upon the preventive aspects of medicine

Surgery, Medicine, and Midwifery —It is proposed to postpone the consideration of the teaching arrangements in the great clinical subjects In discussion much will depend on the reply to the question whether or not the teaching of the earlier sciences can be so modified as to give the clinical teachers a more adequate opportunity than they possess at present of satisfactorily overtaking their subjects In the medical curriculum the two groups of necessity react on one another Further, it is not proposed at the present stage to issue any special recommendations Before any change can actually be made in the curriculum general agreement is essential, and to the possibility of that attainment the expressed opinion of the Council is probably the best guide In view of the important issues involved, it is hoped that the various points raised in the Report will be fully discussed in the course of the session

The Report has been prepared by the Chairman after an analysis of the replies received from the teaching bodies The Committee is of opinion that the questions which have been raised involve the revision of the whole curriculum in medicine, and suggests that the Council should remit to it for further report the consideration of the methods under which the necessary revision may best be carried out

Dr. Mackay, in presenting the Report, outlined the history of the movement towards an improved curriculum, remarking that the diagnosis of morbid conditions was not even to day receiving the instruction and the attention it should The matter needed long and careful consideration, but the present was an opportune time to make a beginning. The curriculum had been divided into two groups of subjects, the chief being the clinical, and, secondly, all the other subjects which could be regarded as ancillary to them. The real teacher of medicine was the clinical teacher, all the others having as their function the preparing of the student's mind for the reception of what would constitute his life's work. With regard to the preliminary education of the student, the Report suggested that the Council should consider whether there would be an advantage in not allowing a student to begin his medical course until his eighteenth year, thus allowing him to receive the previous training which would fit him to receive the instruction for his chosen work. In all the other great countries the commencing age was higher than here. If the age were raised the student might be called upon to pass a more extensive preliminary, and possibly physics and inorganic chemistry might be included in his school work, thereby greatly relieving the pressure in his first medical year. An important point was the proper coördination of the different subjects in the curriculum, not only to avoid overlapping, but with the view to seeing that the student received instruction in any one subject at the time he was interested in it and was able to benefit most from it. For instance, many parts of clinical surgery could be taught with anatomy, for in the absence of a clinical interest and application, anatomy was apt to be a mere matter of memorising It could advantageously be largely taught on the living body. In physiology too much attention was paid to minute experimental details; there should be rather a concentration on the normal physiology, including percussion, heart sounds, and estimation of blood pressure Pathology, he held, might be divided into general and clinical. It had been suggested that the ground covered in pharmacology could be much reduced by paying particular attention to 40 or 50 of the more important drugs, thereby reducing much of the memory work. Sir George Newman, in his Memorandum proposed that pharmacology should be taught in the laboratory as a continuation of physiology, together with other subjects such as hygiene, dietetics, hydrotherapy, and electrical treatment. Dr. Mackay asked the Council to discuss the report fully.

Dr. MCVAIL seconded.

Dr. NORMAN WALKER spoke of the importance of the report, and on his suggestion the Council resolved itself into Committee to allow of an unfettered discussion.

Sir NORMAN MOORE reminded his colleagues that their object was to lay down the parts of knowledge which were necessary to be acquired before men were considered fit to practise their profession. That predominant function had been somewhat lost sight of in some of the discussions at Council meetings. All sorts of reasons had been advanced for either adding subjects to the curriculum or taking subjects from it, or modifying the degree of knowledge required. It must never be forgotten that the element of time was an important one, otherwise a man might go on until he was 35, and still have some subjects left to master. In present conditions in the country and in practice, men should not be required to study more than five years in order to qualify. How much time ought to be given to medicine, surgery, and midwifery? With regard to preliminary education, he laid stress on whether the youth had received such education as to make him wish to enter a university With reference to chemistry, physics, and biology, he would like to hear that question discussed first from the point of view of what the mind could retain. Men in practice seemed usually to have retained but little of what they had been taught about them. Formerly, biology as a subject was not required at all. Anatomy and physiology were most practical subjects, and they should be taught with a definite relationship to professional needs during the whole time He would like to see anatomy so taught as to use up as little as possible of the five years, while at the same time having a very definite effect on the mind of the student. Moreover, the scarcity of bodies made it necessary to have a change of method in pursuing this study. There was a tendency to allot to physiology a bigger place in the curriculum than it deserved, and he agreed that leading principles should be concentrated upon He implored the Council to keep always in mind the producing of a thoroughly trained medical man.

Sir JAMES HODSDON agreed that the Council had to legislate for the minimum, and that any recommendations made were, at this stage, no more than suggestions. It would be conceded that men were not being turned out as practitioners in accordance with modern notions, especially on the subject of preventive medicine. The chief reason was the tendency to encroach on the fifth year of study, and to teach earlier subjects in more or less "water tight" compartments, as if the students were going to be specialists in each one. His view was that there should be fewer lectures and less didactic teaching, and the giving of more tutorial and practical instruction. The student was burdened with examinations throughout the whole of his course. He thought the records as to the way the student had been doing his work should be available at the examination, it would tell the examiner much more than he could ascertain by ten minutes of questioning A point which members of the Council had to ask themselves was whether the earlier subjects could be somewhat curtailed, so as to give more time to those embraced in the Finals, or whether there should be a rearrangement of subjects to secure better coördination.

Sir JOHN MOORE said he had felt in recent years that the five year curriculum had been essentially a retrograde step so far as the attainment of a knowledge of medicine was concerned. The prime matter in the mind of the student was as to how he could pass his examinations. But clinical work could not be learned from the lips of a teacher. In his experience there had recently been a marked falling off in actual direct clinical work in the wards, and the following up of cases to see the results of treatment To have a multiplicity of examinations, in his view, was wrong. The place for the ancillary subjects was the school, and he agreed with those who would postpone the commencement of medical study to at least the seventeenth year.

Sir GEORGE NEWMAN reviewed the whole subject. He warmly agreed with Sir Norman Moore that in considering the medical curriculum members of the Council had to consider the product, which should be a clinical product. The question was, What kind of medical man did the times require for the immediate future? The new demands which the State had made on the medical man must be faced. Public health was the communal aspect of preventive medicine. The State was now making demands on two-thirds or three-fourths of the profession, as against the former demand of one-fourth. The demands were, in the main, clinical. No greater mistake could be made than to contend that State medicine was non-clinical; he would view with great concern any attempt to divorce State medical work from clinical work. He wished to put in a plea for a recognition of the importance of the preliminary science subjects; there should be the desire to strengthen rather than weaken them. The practitioner needed to be more biological, more chemical, rather than less; more, rather than less, ready to apply to his work the great principles of physics and chemistry. The time was now more than ripe to consider a broad and generous reform. He thought the curriculum should be lightened at both ends. At present the student was not being given time to think or digest knowledge—time for real study; it was a rush from the beginning of the first year to the end of the fifth. True culture or true learning could never be acquired on the priniciple of a general scrimmage. His second suggestion was that there should be an attempt to coördinate the preliminary scientific and intermediate subjects with each other and with the clinical, and to make them much more applied. Thirdly, the Council should consider a reorganisation of clinical teaching, so that the student could have of the best, not the residuum; and that the teacher should not give of his best to his practice, but to his university. Fourthly, he wanted to see provision for the student to have an ampler education in venereal disease, tuberculosis, maternity and infant welfare, orthopædics, and mental diseases—he advisedly omitted mention of specialties. Many men were being turned out of the medical schools unequipped in the subjects he had named. In the combat with venereal disease, for instance, no solution would be found until the mass of practitioners were equipped to deal with that disease; its roots were too deep, and the provision of clinics was not a solution. Much the same could be said about the others. His fifth point was that there should be some kind of post-graduate equipment and education, both to assist towards specialisation and to continue the ordinary medical education of the practitioner. His last word in debate was that there should be reformation of the examination system; it should be made to follow the training, not to decide it and lead it. It should include the process of preparing the student, should be made not a hazard, but a certainty. This would alter for the better the whole of the student's outlook; it would bring the student to his books, to his specimens, to his cases and his bedside work in an entirely new spirit.

Sir GILBERT BARLING said that at Birmingham they had arranged that in all the categories except medicine the student should carry his markings with him, the exception being due to the fact that in medicine an extern examiner coöperated, and he could know nothing of the student's previous work. He mentioned the reference in the Report which implied that the future general practitioner is possibly not receiving such a training as will qualify him to diagnose and treat disease in its very earliest manifestations; such a passage might have been taken from contributions which one had become accustomed to in the *Times* lately. The tendency was to throw on the general practitioner the most difficult part of the practice of medicine. Would the education which could be given to the student enable him to recognise with certainty the earliest beginnings of disease? That needed the best possible training which medicine and surgery could provide. He thought weeks should be devoted to the anatomy of the brain and spinal cord. Nothing could be cut out of the clinical curriculum as it now existed, but it was sure to be added to. This was not the time to ask people to devote great additional expense to training; but if the number of candidates for the profession were to greatly increase, then the curriculum could be boldly extended.

Dr. NORMAN WALKER moved the adjournment of the debate.

FRIDAY, JUNE 4TH.

Report of the Pharmacopœia Committee.

Sir NORMAN MOORE submitted this report and pointed out its main provisions, saying that the sales of the Pharmacopœia to the end of May, 1920, had been 1582 in seven months, or 36,852 since the date of publication. The Committee had agreed to approach the Government with the suggestion that a public institution should be established for the official standardisation of such remedies as serums and vaccines. The Minister of Health had now taken the matter up and appointed a special committee to advise him on the measures which should be taken. Sir Norman Moore made grateful reference to the help which Sir Nestor Tirard had rendered to the Committee over a long period.

Sir JOHN MOORE seconded the resolution for the adoption of the report and it was carried, as was also a proposition to appoint Sir Nestor Tirard as secretary of the Committee at a due remuneration.

Resumed Debate on the Report of the Education Committee.

Dr. NORMAN WALKER, in resuming the debate, said he had recently returned from the United States, where there was no General Medical Council, and where every university was free to do what it liked in the matter of medical education, always, however, keeping in view the passing of the examination, failure in which was held to be to the discredit of the university. They were also under the voluntary influence of an Association under which schools were classified. The success of a school depended on its remaining in category A. One effect of this classification was, that whereas formerly there were 439 schools, the number was now 89, of which 72 were classed A. The standard in these latter was high, and the professors in them must be full-time professors. The association between the hospitals and the universities was, in most places, very close. To qualify for Class A schools, students must have had four years of high school education and two years collegiate education—some schools required three years. All Class A schools included chemistry, physics, biology, and a foreign language. The medical curriculum extended over four years, but the student was not admitted to the examination of the National Board until he had served one year as an intern in either a hospital or a laboratory. The supply of bodies there was so good as to allow half a body for each student to do his anatomy on. Much stress was laid there on embryology, and in anatomy great attention was paid to neurology, and this was carried well into the third year. The same was true of bacteriology and of biochemistry. Most of the schools had a whole-time professor of biochemistry. The laboratories were beautifully equipped, and money seemed to have been readily forthcoming for them. He was much interested in one of the classes on operative surgery. The class was divided into sections of 80 students, and there was a rotation of duties as surgeon, assistant surgeon, anæsthetist, and family doctor. Should the surgery—on the cadaver—be voted unsuccessful, an appointed coroner held an inquest. And in that land of liberty the students were more orderly than here, more definitely responsive to authority. Great care was exerted in admitting students, hence the best material was obtained for securing good results. There were physicians and surgeons on the "whole-time" staff, but they had consulting rooms in the hospital and received their private patients there, making a good income thereby. These professors had all the resources of the hospital at their disposal. Dr. Walker said he was a great believer in the value of good lectures, though there were subjects on which the number of lectures was overdone. He found in the States an amount of coöperation between the university and the city which was most interesting. The city of Cincinnati supported its university, and was responsible for the salaries of the university medical faculty and for the whole of the medical treatment of the city. All the special hospitals were in association with the teaching hospital, and the students had access to all of them. Dr. Walker thought chemistry, physics, and biology should be taken before the student commenced his study of medicine. There were now too many medical students, and there would soon be far too many doctors, and the taking of those three subjects quite early would enable men to find out soon if they were not cut out for a medical career. He would like the medical curriculum to be of four and a half years' duration—he would even be content with four, because there was a way of lengthening the curriculum by making the terms longer; 32 weeks for study out of the 52 was not a large proportion. The session at Minnesota University went on all the year round, and the holidays accounted for only seven weeks. This would mean more teachers, because the same teachers could not be expected to continue during the whole year. Certainly there should be more paid professors' assistants. Also the present limitation of hours for teaching in hospital should be removed. He regarded the "intern year" as a splendid thing. We had many hospitals where no teaching was done, yet nothing so raised the status of a hospital as to make it a teaching institution. In America medical societies arranged for professors in specialties to attend the town at definite dates, when practitioners brought their cases for consultation and instruction. This idea was welcomed and was growing. He concluded by expressing a warm eulogium on the Mayo Clinic.

Dr. RUSSELL WELLS spoke of his 17 years on the Senate of London University, and said the time had fully arrived for taking stock of the position in regard to medical education, and for ascertaining wherein their deficiencies lay, at the same time preserving our undoubted excellencies. The literary standard required in the preliminary examination for medicine—modified second class College of Preceptors—was very low, so low as to constitute a disgrace; the standard accepted was refused by the solicitors, accountants, and even auctioneers and estate agents, yet it was the portal of a profession which demanded high intellectual attainment. He thought students might be encouraged to enter hospital at the age of 18. It was the first year which determined the attitude of the student towards his work. He strongly urged that the various subjects should be taught from the standpoint of their application to medicine. And it was not desirable to make one series of lectures do for two sets of students. Chemistry should run through the whole course, and he would like to see some form of biological chemistry in the final examination. The same applied to anatomy and physiology.

Dr. MCVAIL expressed the hope that Dr. Norman Walker would publish for the benefit of the profession what he had learned as to American methods. When he, the speaker, first moved in this matter it was to ascertain whether the practitioners of the future were being taught to fully realise the opportunities lying before them of dealing with the early stages of disease. The question of lengthening or otherwise modifying the curriculum could very well be considered in a practical way by a committee of this Council, for their body embraced specialist teachers in the different branches, and they could be given power to coöpt outside help. The subject was the most important which had come before the Council for a quarter of a century.

Sir ARTHUR CHANCE considered that the preliminary education was very important; if a man was well educated he had already advanced one-fourth of the way towards being a practitioner. Examination would not make him worthy, any more than measuring a man would make him taller. The teacher had so far not received much attention in this discussion. He did not know a professor in Ireland who received half as much as he could make by private practice. It must be remembered that the five years' course was the minimum requirement, but the average time taken to qualify was: in England, 6½ years; in Scotland, 5 years 8 months; in Ireland, 5 years 11 months. He considered the first need was for a weeding out of the curriculum, to take out the things least useful and valuable, and concentrate on real essentials. Preliminary science should be taken before commencing medical subjects, but there was a danger of that science being taught in a perfunctory manner. It need not be very deep, but, so far as it went, it must be sound.

Dr. LITTLEJOHN said this Council was largely responsible for the present position of medical teaching in the country, because whereas in 1869 it gave a lead as to what ought to be done, it had not since moved with the times, but had rather kept back medical teaching as desired by those who would have made progress; it had shown no elasticity. It would be an advantage to dispense with the water-tight compartments. For instance, anatomy should not necessarily be finished by a certain time. He objected to waiting two or three years for the change; in Edinburgh they were waiting for a lead from the Council so that they could establish certain professorships, such as one in biochemistry. Nor would he slavishly sit at the feet of America in this matter, as at one time we did at the feet of Germany; he contended that the merit was not all on one side. He had long advocated an intern year for students, the value of which he pleaded.

Dr. MACDONALD spoke from the standpoint of the general practitioner, and declared that a number of men were sent out as general practitioners who were not capable of fulfilling the duty required of them, and that failure he attributed to their training not having been practical enough; they were not taught the interdependence of the various subjects and their general applicability to medicine. There were certainly not enough professors and teachers; their numbers ought to be quadrupled.

Dr. DEAN said all felt that the present curriculum was badly overcrowded; something must be omitted and other means of shortening carried out if any attention at all was to be given to new subjects. He hoped any future questionaires to the teaching schools would raise the point whether any course could be omitted altogether. At present a disproportionate amount of time was spent in the lecture-room, and there was a good deal of overlapping. With regard to pharmacology and therapeutics, Sir George Newman considered that teachers should be skilled in and be able to teach the values of dietetics, rest, hygiene, hydrotherapy, electric treatment, Finsen light, X rays, radiotherapy, remedial gymnastics, thermotherapy, climatology, open air, massage, and psychotherapy, as well as giving special attention to the actions of vaccines, antitoxin serums, thyroid extract, and salvarsan. It required excessively able teachers to deal with all these. If it was intended that these subjects should be dealt with in one course, the arrangement was an unnatural one. In every medical school he would like to see a committee of coördination, at which the various teachers would meet and learn each other's scope. In chemistry the medical student should be taught in a separate class; not medical chemistry, but chemistry for medical students. If there was to be any curtailment, he asked that it should not be at the expense of chemistry and physics; it could be done at the expense of zoology and botany. If men did not preserve their knowledge of physiology in later life, that seemed to show that their teaching had been too theoretical. With regard to the final subjects, there was room for much more collaboration and coöperation between the teachers in pathology, medicine, surgery, and gynæcology; and he thought more attention ought to be given to morbid physiology.

Professor THOMSON asked the Council to keep carefully in mind that it was the minimum they had to settle.

Dr. CATON thought there were signs that more men would try to enter the profession than there was room for. The Council should ensure that every portal of entry to the profession should be of sufficient type, so that all who passed through it should have the capacity to take due advantage of the subsequent training. He lamented the almost entire disappearance of classical studies in many cases. Greek and Latin were of great importance in developing mind and character, even if only pursued moderately. In the teaching of chemistry, physics, biology, and botany, those subjects were now so extensive that the teaching of them to the medical student should be directed always to his life-work. He hoped the preliminary examination would be so framed, and that cramming would avail less than ever.

Sir **JAMES HODSDON** expressed his appreciation of the admirable Report. He discussed the two forms of anatomical nomenclature being used, and urged that there should be a uniform nomenclature on the subject for all English-speaking peoples. There was a strong feeling in many quarters that the old system should not be departed from.

Dr. **DIXON** said he held very strong views about the nomenclature used in anatomy, but so strongly did he feel the need for uniformity that he would be willing to adopt terms he did not like in order to secure it. He hoped the final report on the matter now under discussion would be in such a form that it could not be thought to hinder the universities from making suggestions, because the conditions in different places varied enormously. In regard to anatomy, there was need to stimulate the interest of the student in every possible way; therefore the Council should not insist on that subject being taught as a science in itself.

Mr. **E. B. TURNER** said the student must be taught to think for himself; the knowledge which a man got for himself was the knowledge which would abide with him. He had a great belief in the value of a classical education. Unless the general practitioner received training in preventive medicine he would fail in the never-ending fight against disease. Patients suffering in the incipient stages of disease always went to the general practitioner first, and it was he who went into patients' homes and knew their conditions and surroundings.

Professor **T. W. GRIFFITH** agreed that the study of chemistry, physics, and biology should be transferred to the school, but there the teaching should be done by those who were fully competent for the work. The lectures should be very valuable, and they should contain matter which was not to be found in the ordinary text-book; he had a good deal of contempt for mere text-book dissertations. He would like to see the number of lectures on medicine reduced and their quality raised; the lecturer should know months in advance what was expected of him, so that he could give careful preparation. Much had been said about preventing overlapping, but there might be overlapping of a good kind, and the teacher should not mind kicking over the traces a little. The lectures on anatomy and physiology should be illuminated by references to practical points.

Professor **LEATHES** said that after a long discussion at Sheffield the teachers of anatomy and physiology had offered to shorten the amount of time they had required at the beginning of the course, and the net result of the suggestions was that the student would have three years to devote to clinical work. During the third and fourth years there would be a certain amount of laboratory instruction. Their proposals involved the breaking down of the rigid boundary wall between anatomy, physiology, chemistry, and physics, and they had instituted a chair of pharmacology, the occupant of which would be whole-time, except in so far as he had duties in the hospital.

Sir **JENNER VERRALL** said the Council must beware of aiming at a standard which the public would not be prepared to accept; and, on the other hand, it must always be remembered that the Council had to legislate for a progressive science. The men turned out for practice should have a clear recognition of the limitations of their own knowledge, so that they should not essay to deal with what was beyond their competency.

Dr. **ADAMS** expressed his warm support of Sir George Newman's contention that the teachers should give the student marks for his work throughout his career; that in itself would help to a better appreciation of the candidate's capacity, and would largely obviate the nervousness from which so many suffered.

The **PRESIDENT** read to the Council the only document which it had to guide it on this matter; and this stated "that the period of study shall be a period of bona fide study of not less than five years," and it proceeded to enumerate the subjects. There was nothing of a "cast-iron" nature in that regulation. It had stood as an instruction since 1893.

He then reported from Committee to the whole Council, and, on the proposition of Dr. **MACKAY**, the following recommendation was submitted:—

> "The Committee begs to submit to the Council the foregoing report on 'the teaching of the preventive aspects of medicine,' which has been prepared by the chairman after an analysis of the replies received *from the teaching bodies*. The Committee is of opinion that the questions which have been raised involve the revision of the whole curriculum in medicine, and suggest that the Council should remit to it for further report the consideration of the methods under which the necessary revision may best be carried out."

Sir **NORMAN MOORE** seconded, and it was agreed to, and in addition that the Committee coöpt such members of the Council as it was felt could render it service.

It was further agreed that copies of the report be sent to the various schools, and such additional copies as might be asked for up to ten.

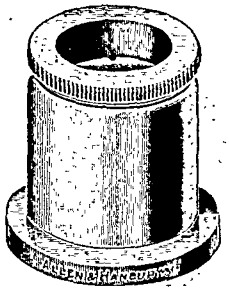
Colonel King was reappointed Registrar, and the President was authorised to deal with the work of the Council until the next session.

New Inventions.

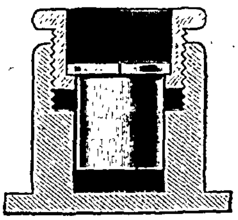
MECHANICAL CELL FOR MICROSCOPING CEREBRO-SPINAL FLUIDS.

THIS device makes possible the scrutiny of every cell and bacillus contained in a column of cerebro-spinal fluid 1 cm. in depth.

A cover-glass (not too fragile) is placed at the bottom of the cell (see diagram), which is then filled to the brim with fresh cerebro-spinal fluid. After an hour or two the cells and cocci will have sunk and will be lying evenly on the cover-glass. The milled head is then gently unscrewed; this causes the cell to rise, creating a vacuum beneath it. Provided the screw is air-tight (a trace of vaseline on the thread ensures this), the supernatant fluid falls through the little channels provided into the well below the cell. A few more turns of the screw detaches the cell from its base, and if it is then placed in front of the fire its wall will drop, leaving the cover-glass on a little altar of brass, where it quickly dries. The ordinary routine is then followed. In staining no heat should be applied lest some cells be washed off.



SCALE $\frac{2}{3}$



SECTION

In collecting the fluid the first blood-stained portion should be rejected. If the cerebro-spinal pressure exceeds 12 inches by my cerebro-spinal manometer (Messrs. Allen and Hanburys), meningitis or tumour or abscess is almost certainly present. Even if the cells are not counted, by the regular use of this apparatus an accurate quantitative impression of the number of cells is obtained.

The apparatus is specially useful in cases where tubercle bacilli are, or may be, present; for in tuberculous meningitis a spider-web clot often forms which entangles the tubercle bacilli, and an attempt to spread out this clot thinly inevitably ravels it up into a tangled mass which cannot be scrutinised microscopically. If the cerebro-spinal fluid looks turbid to the naked eye, it will need dilution before using the instrument.

Messrs. Allen and Hanburys supply the instrument not only as figured above, but also the earlier model, shown at the Neurological Society, of which the design and action are more self-evident.

My thanks are due to Mr. F. M. C. Lewis for the excellent design.

FRANK C. EVE, B.A., M.D. Camb.,
F.R.C.P. Lond.

Hull.

THE LANCET.

LONDON: SATURDAY, JUNE 19, 1920.

Hospital Sunday, June 27th, 1920.

THE annual collection of the Metropolitan Hospital Sunday Fund will take place on Sunday, June 27th. It is not necessary to press the urgency of its appeal upon our readers, for they are fully aware of the conditions of narrow margins, of debt, and of mendicancy under which the voluntary hospitals are carrying on their work. The general public is equally alive to the position, the closure at the National Hospital for Paralysis and the threat of similar disaster at the London Hospital only putting accents upon a familiar text. Alas! the familiarity of the text is a source of weakness, not of strength, and we beg our readers not to assume that an evil because of its long life is necessarily eternal, and that the aggravation of an evil is no measure of its incurability. All know what the situation is in which the hospitals find themselves, and upon its causes there is no need to dwell. The ordinary householder and the members of his household are not likely to forget the risen and rising price of the necessaries of life, and the daily difficulty felt by many in trying to make both ends meet. We cannot ignore that difficulty, but we ask that it should not close any purses to the hospitals, but rather that it may stimulate sympathy. The anxiety which oppresses the hospitals weighs in like manner on those responsible for the care of the helpless sick and disabled, and it is to the sympathy of persons able to appreciate the situation that appeal can be made with greater assurance. And if the hospitals, through the stress of the times in which we live, lose perforce some of their old patrons, they should gain new ones, on whose ears the claims of generosity must fall loudly. There are newly rich as well as newly poor. The war, and the manufacturing and commercial enterprises which it brought into being, have left many to whom high prices do not make as much daily difference as to their neighbours. Those richer in 1920 than they were in 1914 are sometimes reproached with the fact. The needs of the voluntary hospitals offer a splendid opportunity to show that such obloquy is undeserved. The new rich can prove that in the struggle to become wealthier they have not forgotten the days when they were poorer, and that they are able to feel for those who in the humbler classes of the community can only find relief in the hospitals when struck down by serious physical disability. It has been said that old names have passed out of the lists of subscribers to hospitals through death and the circumstances produced by the war, and that the names of those who are now for the first time able to give freely in charity have not taken the place of these worthy predecessors. That is a serious charge against men and women whose freshly acquired wealth must almost inevitably place them in positions of influence in the community. They are called upon to set an example to others, and an example of generous charity has ever been one which has had wide influence for good.

On Hospital Sunday the appeal is for the worthiest object that any man's charity can have. Money is asked for to save from death and to restore to health those who without the aid of the hospitals would have to meet the grim alternative of dying and leaving their families to face the world unprotected. It is to be given without expectation of repayment, but it need not be forgotten that the generous giver may some day have his reward. In his hour of need, for himself or for his wife or child, he may require the help of the highest medical or surgical skill. It will be knowledge acquired in the wards of a hospital which will come to his aid; it will be science developed in the various departments of a hospital which he has helped to maintain that will enable his disease to be traced to its source and combated. The working classes will surely appreciate these facts, and we take this opportunity of recording their increasing support of the voluntary hospitals. But while no one denies that some sections of the working classes have profited more than most of their fellow subjects by the war, and that the general higher wages may allow of a better scale of living among these than they enjoyed before, do not let us forget that their margin, with increased prices, is small, and that the raised conditions are not only their right, but necessary to the improvement of public health, which, God knows, called loudly enough for it. We are a long way from eliminating poverty from our midst. We are a long way from possessing a working class able to pay for such aid as the hospitals can give, even though workers may be more prosperous than their forefathers were in the days when the hospitals were founded. The question of State control is not here under discussion; on this occasion we are speaking in behalf of that grand voluntary system, the supporting and supplementing of which is, we know from the best authority, the design of the Government and an integral feature of future legislation. The Report of the Consultative Council on Medical and Allied Services to the Ministry of Health indicates the direction of medical thought and intention, while the endorsement of the ideals contained in that document by the public press shows that the medical view and the popular view are one in intention. The voluntary hospitals are essential to our society, and their needs are public needs, as much to be met out of public generosity as out of taxes and rates.

The present situation of the voluntary hospitals of the metropolis is a terribly anxious one. Their financial position is serious, but not desperate. The war has crippled them as it has crippled many of those who used to help them freely, but they can point to their record in the war with pride and claim from all classes a double measure of support in difficulties greater than those which they have faced before. Hospital Sunday brings an opportunity to all. It is primarily the day on which those give who attend religious worship where collections are made, but it is not necessary to hold back from contributing because the collecting box is not rattled in the streets. Only let those who have the Metropolitan Hospital Sunday Fund brought to their notice in church or chapel not forget to press its claims upon others who are absent; and let those who have not given before initiate an annual custom with a substantial donation. Ten years ago we should have looked upon a collection of £100,000 as a record on which the public could be congratulated. If double that amount were to be recorded for 1920 it would still be inadequate when the change of conditions is considered. It is not the "usual amount" that all are urged to give. Let them double or treble it. And above all let no one hang back because of recent melancholy cries that the voluntary system is doomed. It has received, as a matter of fact, a new lease of life by being found to be a necessary part, even a nucleus, of the immense developments that are projected.

The Diagnosis, Prognosis, and Treatment of Nephritis.

It has been somewhat of a reproach to medicine that until recently the investigation of surgical diseases of the kidneys has been more scientific, more efficient, and more practical than that of the strictly medical diseases of these organs, with the result that surgical diagnosis and treatment have been more satisfactory and more successful. This has been largely due to the fact that tests for renal efficiency have been developed by surgical urologists for the express purpose of differentiating bilateral from unilateral disease, and for determining the affected side in the latter case and the efficiency of the remaining kidney. On the medical side much attention has been paid to the quantity and composition of the urine and the presence of albumin and casts, but it is only recently that the question of renal efficiency has been investigated in these cases. Much useful work has now been done on these lines which has not yet reached the text-books, and being still only to be found in monographs and papers in various medical journals, it remains outside the ordinary routine of medical procedure. We publish in this week's issue of The Lancet an interesting and important paper by Dr. H. MacLean and Dr. A. E. Russell, which we commend to the notice of our readers, since it not only gives a review of some reliable methods for investigation of the various aspects of the renal functions, but also contains practical and explicit details of their application and use. Incidentally it affords most valuable data in regard to diagnosis, prognosis, and treatment, which should be of the greatest help to the practitioner.

At the outset Dr. MacLean and Dr. Russell point out that the specific functions of the kidneys known to physiology comprise three different processes—the elimination of the waste nitrogenous products of metabolism, the removal of acid products, and the maintenance of the necessary concentration of salts in the fluids and tissues of the body. It is a point of great interest to note that these functions are variously involved in the different forms of nephritis. In severe cases of chronic interstitial nephritis there is a definite retention of nitrogenous waste products in the blood, with a diminution of the acid-excreting function. On the other hand, in parenchymatous nephritis there is no evidence of any retention of nitrogenous bodies in the blood or of any failure in acid elimination, but there is usually inability to excrete the normal amount of salt. The bearing of these observations upon the clinical and chemical phenomena of the two varieties of nephritis is developed clearly by the authors. The retention of urea and other nitrogenous products in the blood due to defective elimination in cases of chronic interstitial nephritis can easily be demonstrated, and the urea in the blood estimated. The absence of any defect in the function of the kidney dealing with salt explains the practical absence of œdema in this form of nephritis. In parenchymatous nephritis, on the other hand, the chief difficulty appears to be in the excretion of the necessary amount of salt, and as an inevitable result there is a retention of water leading to œdema, which, together with albuminuria, is the characteristic feature of this form of the disease. In the investigation of cases Dr. MacLean and Dr. Russell recommend the use of salicyl-sulphonic acid as the best and simplest test for protein in the urine. They give directions for the examination of casts, but point out that the variations they show are not necessarily of much value in assessing the degree of renal inefficiency. For this purpose they bring forward three tests—the estimation of urea in the blood, to which reference has already been made; the new "urea concentration test" of MacLean and de Wesselow; and the estimation of the diastatic activity of urine, often referred to as the urinary diastase test. The second of these is strongly recommended by the writers of the paper on account of its simplicity and reliability, and since it has been used in nearly 3000 cases their opinion must necessarily be of great weight. The test involves no more complicated procedure than the administration of 15 g. of urea dissolved in about 100 c.cm. of flavoured water, and the estimation of the urea in samples of urine passed one hour, two hours, and occasionally three hours afterwards. Obviously it does not demand either much time or a difficult technique, and it can easily be made a routine procedure in the investigation of cases of renal disease where necessary. The diastase test also involves no very difficult procedure, but to be accurate requires a sample of the 24 hours' urine. Dr. MacLean and Dr. Russell find a combination of the three tests very useful. We are glad to notice that they insist on the necessity of due correlation of the data so obtained with the results of a thorough clinical examination.

As affording some definite measure of renal efficiency, and indicating which of the kidney functions are involved, these tests afford valuable aid in prognosis and in treatment; it is not too much to hope that when the methods have been more widely applied and more fully developed some progress will be made towards a scientific classification of cases of nephritis, for those at present current are partly clinical, partly pathological, and all admittedly unsatisfactory. Dr. MacLean and Dr. Russell give the normal figures obtained with the three tests they recommend, and indicate the departures therefrom which are to be regarded as of grave significance. They state that only one-fourth to one-sixth of the total kidney substance is really necessary to carry out the body needs, and, further, that it is only when the kidney efficiency is reduced to one-fourth or less of its original value that there is any tendency for urea to be retained in excess in the blood. In the light of their researches they have also examined the recent suggestion of Epstein to give a liberal protein diet to cases of parenchymatous nephritis with marked dropsy. They have found that the disappearance of the dropsy which frequently occurs after this diet is always associated with an increase in the blood urea. They therefore suggest that the increased excretion of urine is due to the diuretic action of this urea, and in support of this they find that large doses of urea given to such patients also lead to a disappearance of the dropsy. They are of opinion that the new forms of treatment may enable such patients to survive the dangerous dropsical stage of parenchymatous nephritis and pass into the less distressing chronic interstitial stage. Here they allow that limitation of protein intake may be beneficial, but they strongly deprecate the very low diet to which these patients are often condemned. The paper as a whole teems with practical suggestions and will be of great service to the practitioner who wishes to diagnose and treat his cases of renal disease on sound and scientific lines. It marks a notable advance in our knowledge of certain difficult and distressing diseases.

The Research Defence Society.

THE annual general meeting of the Research Defence Society will be held next Wednesday at 11, Chandos-street, the house of the Medical Society of London, when the chair will be taken by Lord LAMINGTON, the President. Lord KNUTSFORD, the Chairman of Committee, will submit the annual report. That report will show great activity on the part of the Society, and the Chairman, with characteristic humour, suggests that any fall away in the amount of work done before the war may be attributed partly at least to "the prevalent indifference towards our opponents." With regard to that we wish to lay stress upon a point, taken up also by Lord KNUTSFORD, that the Research Defence Society has to reckon with a wider sort of attack from those hostile to research than marked the earlier campaigns. Resistance to experimentation on animals no longer marks the scope of their blindness alike to facts and to the calls of real humanity. The protective treatments, founded on and emerging from such experimentation, are all in the near future likely to be impeded in their beneficial influence by the opponents of the applications of physiology to therapeutics. The admirable address by Sir WALTER FLETCHER on the work of the Research Defence Society, which we noticed in these columns a fortnight ago, shows well that the Society has before it a great task to educate the ignorant, appease the fanatic, and convince the reasonable man. Sir DAVID FERRIER is the honorary treasurer of the Research Defence Society; Mr. STEPHEN PAGET is the honorary secretary, assisted by Captain W. E. ELLIOT, a medical Member of Parliament; and all communications should be addressed to 11, Chandos-street, Cavendish-square, London, W. 1. Money is needed.

UNIVERSITY OF LONDON.—The Senate has resolved to institute a diploma in psychological medicine which shall be open to all registered medical practitioners. The standard in psychological medicine required for the purpose of the proposed diploma will be approximately that required by the University of Cambridge for its diploma in psychological medicine.

GIFT TO BELFAST HOSPITAL.—Mr. George L. Moore, of Forest Hill, formerly in practice as a solicitor at Belfast, has intimated his intention of making a gift of £20,000 to the Royal Victoria Hospital, Belfast, in grants of not less than £1000 every year. A scheme is being formulated for the establishment of a ward to be called the "Moore Ward."

Annotations.

"Ne quid nimis."

A MEMORIAL TO VICTOR HORSLEY.

A MOVEMENT has recently been initiated by friends and former colleagues of the late Sir Victor Horsley towards some form of permanent recognition of his services to medical science, and a preliminary letter appealing for subscriptions to this end has appeared in the daily press. The endowment of a Victor Horsley lectureship has been suggested as a suitable memorial, and the Senate of the University of London as its most appropriate trustees; the exact form of its scope and constitution will be decided by a committee of which the officers are Sir Charles Ballance, chairman, Sir Arbuthnot Lane and Dr. E. J. Domville, joint honorary secretaries, and Sir Frederick Mott and Dr. H. H. Tooth, joint treasurers. The present idea is the foundation of an annual lecture, the subject of which should not be confined to medicine, while it may be delivered by any prominent man in any field of progress. Sir Victor Horsley's death from heat-stroke in Mesopotamia is so recent, and his personality was so forcible, that it would be superfluous to recapitulate in any detail the long list of his activities or to recall the brilliance of his career. It will be remembered that the connexion between myxœdema and athyroidism—long a commonplace of the text-book—was first established by Horsley by means of experimental work on monkeys at the Brown Institute. Here he also carried out extensive researches on rabies. As professor of pathology at University College he developed his bent for experimental research in physiopathology; and when, as surgeon to the National Hospital for Diseases of the Nervous System, he met again his old friend Charles Beevor (who, as house physician, had taught him the rudiments of medicine) together they mapped out the motor area of the orang. Their work, published in the Proceedings of the Royal Society, 1886–7–8, in delimiting the cortical motor areas was for many years the standard reference on the subject. In the surgery of the brain and spinal cord Horsley soon became undisputed leader, and, to quote only one of his specialties, his method of performing the Hartley-Krause operation for extirpation of the Gasserian ganglion brought him much fame. One of his latest discoveries was the recognition of loculated spinal meningeal cysts as a cause of paraplegia, and their operative treatment.

Horsley was a born fighter. And his love of the struggle did not always help his cause. He was a most successful champion of freedom for the physiologist in the cause of research, but the enthusiasm which led him ever to consider his own side right was not in other directions so successful. Therefore wide recognition of his splendid ideals is called for now that he is gone. In his later years he turned to medical politics, being elected as a Direct Representative to the General Medical Council in 1897, and remaining a member till 1907. He did admirable work, but his contentiousness sometimes impeded business. He also took a prominent share in inspiring the policy of the British Medical Association, as represented by the present Articles. His aspirations towards Parliament never materialised, though he held strong political views; but it is difficult to imagine his ever serving under a party chief. He was a man of extreme and tireless energy, at play as well as at work; at his own shooting parties he would walk all his guests off their feet. But more than all sport in any field, he loved his work in the laboratory. Though somewhat critical of the efforts of his colleagues, his generosity to his juniors was amazing; he would spend an incredible amount of time and money in helping a younger man in experimental work, and in encouraging his investigations. His own surgical technique was superb. The son of a Royal Academician, he was no mean draughtsman, and was unusual in being almost ambidextrous with pencil, pen, or scalpel. His optimistic manner inspired the greatest possible confidence in his patients. The man was like a diamond of many brilliant facets—small wonder that their cutting edge occasionally scratched and scarred those with whom he came into conflict. No other medical man of his time was associated with such diverse movements down so many streams of public life. None of the crafts piloted by him ran the slower for his intervention; in fact, he rejoiced in steering them near the rapids, and if necessary through the rapids. There should be no difficulty in obtaining the requisite support to any testimonial to his memory. Among those anxious to be represented will be his scientific colleagues, the Fellows of the Royal Society and of the Royal College of Surgeons of England; his personal friends, and even his personal enemies, who for the most part recognised his sincerity; those women who remember his help in the struggle for political and educational franchise and their younger sisters, more especially those whose admission as medical students to University College Hospital, he did not live to see; and, lastly, members of University College Medical School, from his colleagues to his dressers, who will be proud to perpetuate the memory of a worker who brought so much fame to their school, and who would have rejoiced so heartily in its present magnificent opportunities for development.

APPARENT PULSUS PARADOXUS.

IN pulsus paradoxus the normal increased rapidity of the pulse during deep inspiration is replaced by slowing; the cardiac contractions are correspondingly slowed. In the *Boston Medical and Surgical Journal* of May 20th Dr. Paul D. White has reported an interesting case in which the pace-maker of the heart and the auricles acted normally during inspiration—that is, responded by increased rate—but heart-block was also produced, which led to slowing of the ventricles and therefore of the pulse, simulating pulsus paradoxus. The patient, a soldier, aged 23 years, was admitted to a base hospital on Nov. 10th, 1918, with influenza. There was a history of severe double pneumonia at the age of 5 years, since which time his pulse had always been slow. He said that the fact that his pulse got slower on excitement or exertion had been noted for years. He had suffered from typhoid fever five years ago. Examination showed that he was convalescing from influenza. Polygrams were taken as follows:—

	Auricular rate.	Ventricular rate.
Quiet in bed	43	43
Quiet in bed (later)	40	40
During deep inspiration ...	70	35
Deep expiration	41	41
Immediately after moderate exertion	72	36

The tracings showed that on deep inspiration there were two auricular contractions to one ventricular—a 2 : 1 heart-block. Evidently the auriculo-ventricular bundle was damaged, probably by the disease in childhood, and when the auricular rate rose above a certain level failed to transmit every other impulse. The pace-maker of the heart responded normally to exertion and inspiration by increased rate, but as this was halved in the ventricles their rate actually fell, simulating pulsus paradoxus. During the slow rate of the heart auriculo-ventricular conduction was normal. The slow rate of the pace-maker under ordinary circumstances is noteworthy. Was this due to the disease of childhood affecting the auricle, or did the impaired conductivity of the auriculo-ventricular bundle in some way affect the pace-maker, causing it to settle down to a rate which the bundle was capable of conducting? Volhard[1] has described a similar paradoxical response to change of position. While lying flat the patient had a pulse of 64 and no block; sitting up he had a pulse of 42 with a 2 : 1 block, the auricular rate being 84; on standing the pulse dropped to 22 and became irregular, due to varying degrees of block from 2 : 1 to 5 : 1. Atropin slightly increased the dissociation by increasing the auricular rate, with which the ventricles could not keep pace. Lutembacher has reported a case of "orthostatic bradycardia due to intermittence of conduction of the bundle of His."[2] With an auricular rate of 60 there was no block; at 70 to 80 a 2 : 1 block; and with higher auricular rates 3 : 1 and 4 : 1 blocks.

THE GIFT FROM THE ROCKEFELLER FOUNDATION TO UNIVERSITY COLLEGE HOSPITAL AND MEDICAL SCHOOL.

THE simple facts of the benefaction to University College Hospital and School have been obscured by so much appreciative comment that we propose to set them out baldly. The figures are in themselves sufficiently impressive. The total sum offered is just under £1,205,000—£835,000 to the University College Hospital and Medical School and £369,800 to the University of London on behalf of University College. Of the former sum £400,000 is to be allocated to the building and equipment of a nurses' home, residents' quarters, obstetrical and bio-chemical departments, and the reconstruction of certain existing buildings. The income from the remaining £435,000 will be devoted to the medical, surgical, and obstetric units, to salaries in the departments of bio-chemistry and pathology, and towards the maintenance of beds in the reconstructed hospital wing. The gift to University College is to be applied to the erection of an anatomical institute and to its maintenance. It is estimated that the increased cost entailed on the hospital and medical school, the provision of which is understood to be an implied condition of the benefaction, will amount to, roughly, £20,000 a year. These are the bare facts. The scale of the benefaction is unique in this country, and our appreciation of the honour to one of the most progressive of the London medical schools is not the less because we reserve a detailed discussion until we have been able to study the terms more closely. Such generosity from another country in the cause of scientific research is somewhat humiliating; it is a measure of the neglect of medical education in the past that the benefaction has evoked such widespread notice. King Edward's Hospital Fund has administered larger sums for charitable purposes without so greatly surprising the people. Had the present gift been distributed over all the medical schools in London it would have been less impressive, and certainly less stimulating; had it been offered exclusively for purposes of research or of teaching it would have been less interesting. But the gift is to be regarded primarily as a tribute to the recent attempt at combining research with training. The clinical unit system, initiated by the Board of Education and carried out at University College Hospital in response to official suggestion, was the innovation which first attracted the notice of the two representatives of the Rockefeller Foundation, and it is to its adoption by University College Hospital that the gift is mainly due.

THE MANIFOLD USES OF RUBBER.

THERE is evidently plenty of rubber available now, judging from the offer of substantial money prizes by the Rubber Growers Association as an award for suggestions as to extending the present uses or for encouraging new uses of this singularly resilient material. Incidentally, this should be good news for scientific research, as rubber is, of course, a great adjunct in the laboratories, while also it is an indispensable servant in medicine and in surgery. The offer, however, probably refers to wider uses, for the relative value of suggestions which are deemed practical will, we understand, depend upon the quantity of raw rubber the adoption of these suggestions would absorb, and special considerations, it is announced, will be given to practical suggestions likely to utilise rubber in *large* quantities. (The italics are not ours, but appear in the conditions laid down by the Association.) Our interest, however, lies in the fact that the offer, generally speaking, should mean that rubber is going to be readily obtainable and at a relatively moderate cost, and an ample supply of the material will obviously be a gain to medical science in general. It will be remembered that at one time during the war good rubber was practically unobtainable. There is one thing in regard to rubber, which we hope our rubber producers will give their attention to, and that is its inclination with age to lose its flexible qualities. An old rubber tube, if it has not been constantly used, will frequently be found brittle and full of cracks, and therefore useless for its special purpose. If its flexibility and resiliency could be made permanent the material would be of much greater value. That consideration apart, something is almost bound to come out of this interesting offer, considering the infinity of the applications of rubber, particularly if it should prove that the world's production is such as to make it a cheaper commodity. The assumption arises out of this appeal to the brains of the public to find a bigger outlet for its uses. Improvements in the vulcanising of rubber are announced this week, for which the claim is made that by simplifying the process ways are opened up for new and extensive applications of the material.

A CASE OF LUPUS IN AN ARMY PENSIONER.

A FEW days ago the Minister of Pensions was asked in the House of Commons why treatment had been refused to a private of the Scots Fusiliers suffering from lupus. The recruit had joined voluntarily in 1915 and then was in perfect health, and was passed fit for general service by three separate medical boards. Owing to undue exposure he was sent into hospital with "acute myalgia," and while there lupus developed at the back of one ear. In 1916 he was discharged as totally unfit for service. He was treated at Manchester for lupus, when the treatment was approved and authorised by the Ministry of Pensions. Treatment was continued until last September, when the patient was informed that the Ministry of Pensions did not accept responsibility for lupus and that the treatment was not authorised. Inquiries are being made into the case. If we accept the facts as stated, then it appears clear that the lupus appeared while the patient was in the army, for we may take it that he had no sign of this disease when he was first examined. We are told that he suffered much exposure, and it can hardly be doubted that his service was directly responsible for the appearance of the disease. It is well recognised that the reason that lupus appears very commonly on the nose, cheeks, and ears is due to the fact that these parts are subjected to great variations of temperature from their exposed position and slight blood-supply, and therefore the exposure to which this patient was subjected should be held responsible for the disease. Investigation may show that the facts are not as they were stated, but if the Member who asked the question was correctly informed, we think that the Ministry of Pensions will be acting without the sanction of medical knowledge in disclaiming responsibility.

CONGENITAL STENOSIS OF BOTH URETERAL ORIFICES.

Dr. Isabel M. Wason,[1] writing from the Brady Laboratory of Pathology and Bacteriology of the Yale University School of Medicine, reports the following unusual case. A poorly nourished male infant, aged 7 months, was admitted to hospital for diarrhœa. Physical examination was negative. Death took place 14 days after admission. The autopsy showed double hydronephrosis with dilated tortuous ureters, which ended in cystic dilatations in the small vesical cavity. The ureteral orifices were not visible to the naked eye, but in serial sections they were found to be stenotic and to measure ¼ to ⅛ mm. in diameter. There was also a valve in the prostatic urethra extending from the lower end of the verumontanum to the right urethral wall. In her commentary on the case Dr. Wason states that the presence of a valve formation in the lower prostatic urethra is probably the commonest cause of double hydronephrosis in children. Such an obstruction is usually bilateral, and the urine can only pass through a narrow slit. This gives rise to dilatation of the urethra above this point, dilatation and hypertrophy of the bladder, dilatation of both ureters, and double hydronephrosis. In the present case, however, the valve was found on one side only and did not cause sufficient obstruction to the passage of urine to produce dilatation of the upper prostatic urethra and of the bladder. The dilatation of the ureters and renal pelves was, therefore, not due to the prostatic valve, but to the stenosis of the ureteral orifices, which was possibly caused by a partial overgrowth of epithelium and muscle in embryonic life. Congenital stenosis with cystic dilatation of the vesical end of one ureter is unusual, but to find the condition present to the same extent in both ureters, as was exemplified in Dr. Wason's case, is extremely rare.

THE POSITION OF VETERINARY SCIENCE.

THE Veterinary Surgeons Act (1881) Amendment Bill was read a third time on June 11th, and it seems quite probable that the Bill will pass into law. For some time now there has been a lack of funds available for the Royal College of Veterinary Surgeons to enable it to carry out its statutory duties and to improve veterinary education. The chief object of the Bill is to remedy this situation, and to this end it provides for the compulsory annual payment of 1 guinea by all members of the College who are in active practice in the United Kingdom. The Bill also gives status to the practitioners who were registered under the Act of 1881, and makes them amenable to the discipline of the profession, while it also provides that companies shall not infringe the Act of 1881. Much controversy has arisen about the status of veterinary science in this country, and many educationalists think that great benefit would accrue to the scientific status of the profession through a provision at all universities for the granting of veterinary degrees. But the practical value of a university degree would depend on the facilities existing in a university for the imparting of veterinary instruction. It would only be by a slow and gradual process that these facilities could be obtained, and then if there was not sufficient demand for university veterinary degrees the innovation would be a barren one. The profession only numbers about 3000 all told. It is only a small one, and the prizes securable in it are not likely to cause a great rush of intellectuals to seek entry into its ranks. At the present time two universities grant three veterinary degrees. The Liverpool University grants the degrees of D.V.H. (Diploma in Veterinary Hygiene) and D.V.Sc. (Doctor in Veterinary Science), and the Victoria University, Manchester, grants the D.V.S.M. (Diploma in Veterinary State Medicine), whilst the University of London grants facilities for the taking of the B.Sc. degree concurrently with the M.R.C.V.S. diploma. The real advancement of veterinary science can only follow an educational campaign in the whole realm of animal breeding and rearing. The difficulty is to get the zeal for the benefits of science into the hearts of the workers among animals. Appalling ignorance abounds and sheer laziness increases every day. In quite recent times we have heard of such mediæval enormities being committed as these:—human fæces put on to a festering sore to enable it to heal, a red herring tied to a cow's tail with the object of making it rise, and a sliced raw onion put into a mare's vagina to cure colic. The simple lessons of hygiene in many cases are not known, and even where known in perhaps over 60 per cent. of cases they are not practised. To procure any real advance in veterinary science disease-prevention work by veterinarians needs preceding by a decade or two of disease-prevention instruction and work by stock attendants, stock owners, farmers, dairymen, and agricultural and town landlords. The whole question is one of education, finance, and zeal for hygiene. How long will it take to bring these things up to a really effective pitch? At present the good food that veterinary science provides is not half assimilated by those for whom it is intended, and any culinary refinements will be thrown away or wasted.

---

BRITISH MEDICAL ASSOCIATION:

PROGRAMME OF ANNUAL MEETING.

THE eighty-eighth annual meeting of the Association will be held at Cambridge, under the Presidency of Sir T. Clifford Allbutt, Regius Professor of Physic in the University, who will deliver his address on Tuesday, June 29th, preceding the sectional proceedings.

The Representative Meeting will begin in the Examination Halls on Friday, June 25th, at 10 A.M., and the statutory annual general meeting will be held at the Examination Halls on Tuesday, June 29th, at 2 P.M.

The annual dinner will be held in the Hall of St. John's College at 8 P.M., on Thursday, July 1st. The popular lecture will be given by Dr. G. S. Graham-Smith, F.R.S., on "Flies" at 8.30 P.M. on Friday, July 2nd.

DEMONSTRATIONS.

Laboratory and clinical demonstrations will be given on three consecutive days from 2.30 to 4.30 P.M., commencing on Wednesday, June 30th. The directors of demonstrations are:—

Medicine: Dr. Aldren Wright.
Surgery: Mr. Arthur Cooke.
Physiology: Professor J. N. Langley, F.R.S.
Pharmacology: Professor W. E. Dixon, F.R.S.
Neurology: Dr. E. D. Adrian.
Pathology: Professor Sir G. Sims Woodhead.

THE SECTIONS.

The scientific business of the meeting will be conducted in 12 sections, which will meet on the days indicated from 10 A.M. to 1 P.M., the demonstrations following in the afternoons.

Medicine.

President: Sir Humphry D. Rolleston, K.C.B., M.D., F.R.C.P.

Honorary Secretaries: A. J. Jex-Blake, M.D., F.R.C.P. (13, Ennismore-gardens, London, S.W. 7); W. E. Hume, M.D., F.R.C.P. (4, Ellison-place, Newcastle-on-Tyne); E. Lloyd Jones, M.D. (59, Trumpington-street, Cambridge); J. Aldren Wright, M.D., M.R.C.P. (Director of Demonstrations, 2, Corpus-buildings, Cambridge).

June 30th (Morning Session).—Discussion on the Diagnosis of Nervous Disorders of the Stomach and Intestines. To be opened by Dr. A. F. Hurst.

In the afternoon Mr. J. Barcroft will demonstrate Methods of Analysing the Gases of the Blood and Alveolar Air.

July 1st (Morning Session).—Discussion on the Present Position of Vitamines in Clinical Medicine. To be opened by Professor F. Gowland Hopkins.

July 2nd (Morning Session).—Discussion on the Clinical Significance and Course of Subacute Bacterial Endocarditis. To be opened by Sir Thomas Horder.

An exhibition of specimens illustrating the subject of this discussion will be held in the Pathological Museum.

Surgery.

President: Sir George H. Makins, G.C.M.G., C.B., P.R.C.S.

Honorary Secretaries: W. H. Bowen, M.S., F.R.C.S. (24, Lensfield-road, Cambridge); Arthur Cooke, F.R.C.S., Grove Lodge, Cambridge (Demonstration Secretary); G. E. Gask, C.M.G., D.S.O., F.R.C.S. (41, Devonshire-place, London, W. 1); Gordon Taylor, O.B.E., M.S., F.R.C.S. (15, Harley-street, London, W. 1).

June 30th (10 A.M.).—Discussion: Surgical Treatment of Gastric Ulcer. To be opened by Sir Berkeley G. A. Moynihan and Dr. Charles H. Mayo.

July 1st (10 A.M.).—Discussion: Surgical Treatment of Cancer of the Rectum. To be opened by Mr. W. Ernest Miles and Mr. Grey Turner.

Demonstration in the afternoon by Colonel R. H. Elliot on Glaucoma.

July 2nd (10 A.M.).—Discussion: End-Results of Injuries to the Peripheral Nerves treated by Operation. To be opened by Sir William Thorburn and Mr. Percy Sargent.

Demonstrations will be given in the afternoons by Major Meurice Sinclair on the Treatment of Fractures; by Mr. H. D. Gillies and Mr. Percival Cole on Plastic Surgery of the Face; by Mr. Herbert Tilley on Endoscopy of the Lower Air Passages and Gullet; and by Mr. Arthur Cooke on the Technique of Blood Transfusion.

Neurology and Psychiatry.

President: Henry Head, M.D., F.R.S.

Honorary Secretaries: E. D. Adrian, M.D., M.R.C.P. (Trinity College, Cambridge); E. Farquhar Buzzard, M.D., F.R.C.P. (78, Wimpole-street, London, W. 1); George Riddoch, M.D., M.R.C.P. (10, Alba-gardens, Golders Green, London, N.W. 4).

June 30th (Morning Session).—Discussion on the Early Signs of Nervous Disease and their Interpretation. To be opened by Henry Head, M.D., F.R.S.

July 1st (Morning Session).—Discussion on Dementia Præcox and its Relation to other Conditions. To be opened by Bernard Hart, M.D.

July 2nd (Morning Session).—Discussion on Psychotherapy. To be opened by T. A. Ross, M.D.

Demonstrations are being arranged for two afternoons; particulars will be announced later.

Pathology and Bacteriology.

President: Professor J. Lorrain Smith, M.D., F.R.S.

Honorary Secretaries: A. E. Clark-Kennedy, M.R.C.S., L.R.C.P. (Corpus College, Cambridge); A. E. Gow, M.D., F.R.C.P. (37, Queen-Anne-street, London, W. 1); Helen Ingleby, M.D., M.R.C.P. (44, Welbeck-street, London, W. 1).

June 30th.—Atrophy of the Liver. To be opened by Professor Stuart McDonald, M.D., F.R.C.P.

July 1st.—The Present Position of Cancer Research. To be opened by J. A. Murray, M.D.

July 2nd.—The Bacteriology of Cerebro-spinal Meningitis. To be opened by J. A. Arkwright, M.D., F.R.C.P. (A collection of specimens to illustrate the subject under discussion will be available.)

The afternoons will be devoted to meetings of the Pathological Society of Great Britain and Ireland.

Physiology and Pharmacology.

President: Professor F. Gowland Hopkins, M.B., F.R.S.

Honorary Secretaries: D. V. Cow, M.D. (The Bridge House, Great Shelford, Cambridge); Edward Mellanby, M.D. (32, Addison Mansions, Kensington, London, W. 14).

June 30th.—Discussion on Acidosis in Disease. To be opened by Professor F. Gowland Hopkins.

July 1st.—Discussion on the Physiology and Treatment of Denervated Muscle. To be opened by Professor J. N. Langley, F.R.S.

July 2nd.—Discussion on Quinine and its Derivatives. To be opened by Professor W. E. Dixon, F.R.S.

Naval and Military.

President: Colonel Joseph Griffiths, C.M.G., M.D., F.R.C.S.

Honorary Secretaries: Major A. S. M. Macgregor, O.B.E., M.D., R.A.M.C. (T.) (Sanitary Chambers, Glasgow); Major H. B. Roderick, O.B.E., M.Ch., M.D., R.A.M.C. (T.) (17, Trumpington-street, Cambridge); Lieutenant-Colonel F. E. Apthorpe Webb, O.B.E. (Grafton House, Maid's Causeway, Cambridge).

June 30th (10 A.M.).—Discussion on the Army Medical Service and its Relation to the Education and Training of Newly Qualified Medical Men, to be opened by the President. 2.30 P.M.—The Naval, Military, and Air Force Medical Services will exhibit the new inventions and equipments that arose during the Great War. Each department will be fully represented, and each will be in charge of an officer who will be prepared to demonstrate and explain the exhibits.

Obstetrics and Gynæcology.

President: Herbert Williamson, M.B., F.R.C.P.

Honorary Secretaries: Malcolm Donaldson, M.B., F.R.C.S. (145, Harley-street, London, W. 1); W. R. Grove, M.D. (St. Ives, Hunts).

June 30th.—Discussion on Puerperal Sepsis. (1) Mr. Victor Bonney (London): Introductory Paper. (2) Mr. H. Beckwith Whitehouse (Birmingham): Surgical Treatment of Uterus in Puerperal Sepsis. (3) Dr. A. E. Gow (London): Intravenous Protein Therapy in Treatment of Puerperal Septicæmia. (4) Dr. Leith Murray (Liverpool): Use of Serums and Vaccines in the Treatment of Puerperal Sepsis.

July 1st.—At 10 A.M. there will be a joint session with the Section of Electro-therapeutics to discuss the Treatment of Fibroids by X Rays. Opened by Dr. R. Knox.

Dr. R. Mackenzie Wallace will give a demonstration of the Diastase Reaction on Wednesday, followed by a demonstration from Mr. M. S. Mayou on Ophthalmia Neonatorum.

Tropical Medicine.

President: Professor G. H. F. Nuttall, M.D., F.R.S.

Honorary Secretaries: Charles Frederick Searle, M.D. (67, Bridge-street, Cambridge); J. Gordon Thomson, M.B. (24, Herne Hill, London, S.E. 24).

June 30th (Morning Session).—Papers: (1) Problem of Filariasis, by Drs. Stephens and Yorke. (2) Rôle of *F. bancrofti* in the Production of Lymphatic Obstruction and a Consideration of Elephantiasis from the Pathological Standpoint, by Dr. G. C. Low and Dr. P. H. Manson-Bahr. (3) Dietetic Deficiency and Endocrine Activity, with Special Reference to Deficiency Œdemas, by Lieutenant-Colonel Robert McCarrison, I.M.S.

In the afternoon there will be the following demonstrations: (1) Parasitic Worms, by Dr. R. T. Leiper. (2) Exhibition Collection of all known species of Tsetse Flies, with demonstration dealing with the Morphology and Bionomics, by Professor Newstead. (3) Demonstration of the use of the Mobile Laboratory for Malarial Inquiries in England, by Colonel S. P. James. (4) Paintings illustrating the Treatment of Leprosy, by Lieutenant-Colonel Sir Leonard Rogers.

Medical Education.

President: Sir George Newman, K.C.B., M.D., F.R.C.P.

Honorary Secretaries: S. R. Gloyne, M.D. ("Hatherley," Chalfont St. Giles, Bucks); Professor J. Kay Jamieson, M.B. (Dean of Faculty of Medicine, Leeds).

July 1st (10 A.M. to 1 P.M.).—Address by the President. Discussion: Preliminary Scientific Education in the Medical Curriculum. Openers: Professor S. J. Hickson (Biology); Professor Arthur Keith (Anatomy); Professor Sir Ernest Rutherford (Physics); Professor J. Lorrain Smith (Pathology); Professor A. Smithells (Chemistry).

Venereal Diseases.

President: E. B. Turner, F.R.C.S.

Honorary Secretaries: W. H. Harvey, M.D. (The Dene, Great Shelford, Cambridge); Otto May, M.D. (19, Well Walk, Hampstead, London, N.W. 3).

July 1st (10 A.M.).—Discussion on Venereal Diseases in Women and Children: (1) Dr. Morna Rawlins: Treatment of Veneral Disease in Women. (2) Dr. Leonard Findlay: Venereal Diseases in Children.

In the afternoon there will be a clinical demonstration at the Venereal Diseases Clinic, Addenbrooke's Hospital, and a laboratory demonstration in the Medical Schools under the direction of Mr. J. E. Barnard.

The following Sections meet on Friday only:—

Electro-therapeutics.

President: Alfred Ernest Barclay, M.D.

Honorary Secretaries: E. P. Cumberbatch, M.B., M.R.C.P. (15, Upper Wimpole-street, W. 1); F. Shillington Scales, M.D. ("Redcourt," Adams-road, Cambridge).

July 2nd —Presidential address by Dr A E Barclay Place of the Radiologist in Medicine Discussion on the Diagnosis and Treatment of Paralysis caused by Nerve Injury, to be opened by Mr H S Souttar Joint Discussion with Section of Obstetrics and Gynæcology on Treatment of Uterine Fibroids (see above)

Medical Sociology

President G E Haslip, M D

Honorary Secretaries S Morton Mackenzie, M B (9 Rose hill, Dorking) C M Stevenson, M D (90 Chesterton road, Cambridge)

July 2nd (10 A M) —Sir George Newman will open a discussion on the Future of Medical Practice, dealing with the subject from the point of view of the State The discussion will be continued by Sir Wilmot Herringham from the standpoint of the Consultant Dr Alfred Linnell from that of the General Practitioner Professor F Gowland Hopkins from that of Medical Research and Mr E W Morris, C B E , house governor London Hospital from that of the Hospitals

Pathological Museum

Committee Sir German Sims Woodhead, K B E (chairman), Dr L Cobbett, Dr G S Graham Smith Dr W H Harvey, Mr T S P Strangeways, and Dr H B Roderick M Ch (honorary secretary)

The Pathological Museum arranged in connexion with the meeting will occupy a central position in two temporary buildings in the first court of the Medical Schools It is proposed to arrange the material under the following heads (1) Exhibits bearing on discussions and papers in the various Sections (2) Specimens and illustrations relating to any recent research work (3) Individual specimens of special interest or a series illustrating some special subject (4) Instruments or appliances relating to clinical diagnosis and pathological investigation There will also be a series of exhibits illustrative of war specimens, arthritis cerebro spinal meningitis and parasitology So far as practicable each section will be under the charge of a demonstrator, but exhibitors will have an opportunity of demonstrating their own specimens

Communications regarding material for exhibition should be addressed to Dr H B Roderick, at the Surgical Department, Medical School Cambridge

The honorary local secretaries of the meeting are J. F Gaskell, M.D., F.R C P , The Uplands, Great Shelford, near Cambridge, and G. S. Haynes, M.D , 58, Lensfield road, Cambridge. Communications should be addressed to them at the Medical Schools, Cambridge.

AUSTRALIA

(FROM OUR OWN CORRESPONDENT.)

The Increase in the Medical Profession.

AT the final examination for medical degrees in the Sydney University 49 candidates were successful, while 69 failed. In the University of Melbourne 42 succeeded and 24 were rejected. This represents, with passes in Adelaide, an addition to the ranks of the profession of upwards of 100 practitioners. As the population of Australia is little more than stationary beyond a natural increase, it is evident that the supply of medical practitioners is growing out of proportion to any prospects of practice, although at present there are no signs of overcrowding It is, however, significant that in Melbourne two bodies have been formed, the one exclusively surgical and the other medical, whose object, amongst other things, is to conserve the status of the true consultant against the inroads of general practitioners who devote their spare time to special practice. At least it would be well for British graduates to have some definite prospect before looking to Australia as a possible field of work.

The Health of Miners Tuberculosis and Hookworm.

The Federal and State Governments have jointly equipped an institute to inquire into tubercle among the mining population of Bendigo The objects are —

1 To determine the actual number of persons suffering from tuberculosis in Bendigo and district

2 To ascertain the epidemiological factors involved in connexion with the existing infections These factors would include an investigation into the evidence of infection of persons who have been in contact with infected persons, the relation of the spread of the disease to insanitary conditions, the relations of the disease to mining, &c

3 To determine the relative importance of bovine and of human infection in the distribution of the disease in Bendigo

Dr D. G. Robertson has been placed in charge A hookworm inquiry is being conducted at the same time

At Broken Hill the Broken Hill Mine directorate has opened an investigation into the health of the miners and the conditions under which they work (when they do work, which they have not done for very many months). There is a staff of eight medical men, and over 1000 men have already been examined.

University of Sydney.

Professor J. T. Wilson, professor of anatomy, has been appointed Dean of the Medical School in the place of the late Sir T. Anderson Stuart. The future of the chair of physiology was discussed and referred to a subcommittee for consideration

The Recent Appointments at the Melbourne Hospital.

The recent dissatisfaction with two appointments made to the staff of the Melbourne Hospital on the ground that sufficient attention was not given to the fact that other candidates were returned soldiers, has been allowed to drop after much heated talk and protest. The hospital committee has agreed to a resolution that in all future appointments special preference must be given to applicants with overseas service, but this does not create any new position, and was adopted chiefly to save the faces of those who ought to have known that the most careful consideration had been given to this very point by the advisory committee, but still clamoured for the appointments to be reviewed. The appointments made were not disturbed.

Dr. T. P. Dunhill, C.M.G., who is leaving for London by the *Orvieto* on May 5th, was entertained at dinner by the Victorian Branch, B M A., and the Melbourne Medical Association Readers of THE LANCET will remember the exhaustive study, illustrated by unusually good photographs, on the Surgery of Exophthalmic Goitre, by Dr. Dunhill, which appeared in these columns in December, 1917. Dr Dunhill will take up his duties as assistant director of surgery at St Bartholomew's Hospital immediately on arrival in London.

Dr R J. Bull, who has for many years been director of bacteriology in the Melbourne University, has been granted leave, and will visit Europe immediately in order to inform himself at first hand of bacteriological progress and teaching

April 22nd

URBAN VITAL STATISTICS.

(Week ended June 12th, 1920)

English and Welsh Towns —In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 18 million persons, the annual rate of mortality, which had been 13 2, 12 8, and 11 6 in the three preceding weeks, further declined to 11 0 per 1000 In London, with a population of nearly 4½ million persons, the annual death rate was 10 6, or 0 4 per 1000 below that recorded in the previous week, while among the remaining towns the rates ranged from 5 0 in Ealing, 5 2 in Tottenham and in Edmonton, and 6 0 in Wallasey, to 17 2 in Hastings, 17 4 in Blackburn, and 19 6 in Bootle The principal epidemic diseases caused 272 deaths, which corresponded to an annual rate of 0 8 per 1000, and comprised 89 from measles, 70 from infantile diarrhœa, 48 from diphtheria, 46 from whooping-cough, 14 from scarlet fever, and 5 from enteric fever. Measles caused a death rate of 2 2 in Leicester, 2 8 in Walsall, and 3 6 in Swansea The deaths attributed to influenza, which had declined from 216 to 148 in the four preceding weeks, further fell to 86, and included 21 in Sheffield, 13 in London, and 6 in Carlisle There were 1722 cases of diphtheria and 1642 of scarlet fever under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 1747 and 1635 respectively at the end of the previous week, there were also 4 cases of small pox belonging to East Ham, of which 3 were admitted during the week The causes of 28 of the 3770 deaths in the 96 towns were uncertified, of which 8 were registered in Birmingham

Scotch Towns —In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2½ million persons, the annual rate of mortality, which had declined from 18 4 to 13 6 in the five preceding weeks, further fell to 12 7 per 1000 The 291 deaths in Glasgow corresponded to an annual rate of 13 6 per 1000, and included 8 from measles, 7 each from small pox and infantile diarrhœa, 3 from diphtheria, 2 each from scarlet fever and whooping-cough, and 1 from enteric fever The 75 deaths in Edinburgh were equal to a rate of 11 5 per 1000 and included a fatal case each of whooping-cough and infantile diarrhœa

Irish Towns —The 129 deaths in Dublin corresponded to an annual rate of 16 2, or 2 5 per 1000 below that recorded in the previous week, and included 10 from whooping cough, 5 from measles, 4 from infantile diarrhœa, and 1 each from enteric fever, scarlet fever, and diphtheria The 109 deaths in Belfast were equal to a rate of 13 8 per 1000, and included 4 from whooping cough and 1 each from scarlet fever and infantile diarrhœa

VITAL STATISTICS OF LONDON DURING MAY, 1920.

IN the accompanying table will be found summarised statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease, it appears that the number of persons reported to be suffering from one or other of the ten diseases notified in the table was equal to an annual rate of 6·3 per 1000 of the population, estimated at 4,358,309 persons; in the three preceding months the rates had been 7·7, 7·1, and 6·7 per 1000. Among the metropolitan boroughs the lowest rates from these diseases last month were recorded in Hammersmith, St. Marylebone, Hampstead, Stoke Newington, the City of London, and Woolwich; and the highest in Fulham, Shoreditch, Bethnal Green, Stepney, Poplar, and Lewisham. The case of small-pox notified during May belonged to Greenwich. The prevalence of scarlet fever was slightly less than in the preceding month; this disease was proportionally most prevalent in Fulham, Shoreditch, Bethnal Green, Stepney, Poplar, and Deptford. The Metropolitan Asylums Hospitals contained 1671 scarlet fever patients at the end of the month, against 2266, 1981, and 1795 at the end of the three preceding months; the weekly admissions averaged 228, against 279, 240, and 223 in the three preceding months. Diphtheria was somewhat less prevalent than in April; the greatest prevalence of this disease was recorded in Fulham, St. Pancras, Holborn, Bethnal Green, Poplar, Battersea, and Lewisham. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 2003, 1964, and 1937 at the end of the three preceding months, numbered 1783 at the end of May; the weekly admissions averaged 214, against 240, 260, and 221 in the three preceding months. The prevalence of enteric fever was somewhat greater than in the preceding month; of the 28 cases notified during the month, 4 belonged to Stepney, 4 to Battersea, 3 to the City of Westminster, 3 to Hackney, 2 to Fulham, 2 to Hampstead, and 2 to Wandsworth. There were 18 cases of enteric fever under treatment in the Metropolitan Asylums Hospitals at the end of the month, against 30, 38, and 29 at the end of the three preceding months; the weekly admissions averaged 3, against 6, 6, and 4 in the three preceding months. Erysipelas was proportionally most prevalent in the City of Westminster, St. Marylebone, Finsbury, Poplar, Southwark, Greenwich, and Lewisham. The 38 cases of puerperal fever included 4 in Fulham, 4 in Islington, and 3 each in Chelsea, Hackney, Poplar, Lambeth, Battersea, and Wandsworth. The 12 cases of cerebro-spinal meningitis included 3 in Southwark and 3 in Battersea. No case of poliomyelitis was notified during the month.

The mortality statistics in the table relate to the deaths of civilians actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ended May 29th the deaths of 4145 London residents were registered, equal to an annual rate of 12·4 per 1000; in the three preceding months the rates had been 16·6, 17·6, and 15·4 per 1000. The death-rates ranged last month from 7·6 in Hampstead, 9·4 in Wandsworth, 10·7 in Camberwell, and 11·1 in Hackney, to 13·8 in Stoke Newington, 13·9 in Finsbury, 14·0 in Greenwich, 14·6 in Battersea, 14·8 in Bethnal Green, 14·8 in Stepney, and 23·5 in the City of London. The 4145 deaths from all causes included 350 which were referred to the principal infectious diseases; of these, 115 resulted from measles, 11 from scarlet fever, 67 from diphtheria, 85 from whooping-cough, 7 from enteric fever, and 65 from diarrhœa and enteritis under 2 years of age. No death from any of these diseases was recorded last month in Holborn or the City of London. Among the metropolitan boroughs the lowest death-rates from these diseases were recorded in Chelsea, the City of Westminster, Hampstead, Stoke Newington, and Lewisham; and the highest in St. Pancras, Finsbury, Bethnal Green, Stepney, Bermondsey, and Battersea. The 115 deaths from measles were 52 below the average number in the corresponding period of the five preceding years; this disease was proportionally most prevalent in Paddington, Stepney, Southwark, Bermondsey, Battersea, and Camberwell. The 11 fatal cases of scarlet fever were equal to the average, and included 2 in Islington. The 67 deaths from diphtheria exceeded the average by 28; the greatest proportional mortality from this disease occurred in Hammersmith, Fulham, Hackney, Finsbury, Bethnal Green, and Bermondsey. The 85 fatal cases of whooping-cough were 19 fewer than the average; this disease was proportionally most fatal in St. Pancras, Hackney, Bethnal Green, Poplar, Bermondsey, and Battersea. Seven deaths from enteric fever were registered during the month, against an average of 6; of these deaths, 2 belonged to Hampstead. The 65 fatal cases of infantile diarrhœa were 13 in excess of the average; the greatest proportional mortality from this disease occurred in Kensington, Hammersmith, St. Marylebone, Finsbury, Shoreditch, Stepney, and Southwark. In conclusion, it may be stated that the aggregate mortality in London during May from these principal infectious diseases was 7·7 per cent. below the average in the corresponding period of the five preceding years.

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING MAY, 1920.

(*Specially compiled for* THE LANCET.)

CITIES AND BOROUGHS.	Estimated civil population, 1919.	Notified Cases of Infectious Disease.												Deaths from Principal Infectious Diseases.									Deaths from all causes.	Death-rate per 1000 living.
		Small-pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Erysipelas.	Cerebro-spinal meningitis.	Poliomyelitis.	Total.	Annual rate per 1000 persons living.	Small-pox.	Measles.	Scarlet fever.	Diphtheria.*	Whooping-cough.	Enteric fever.	Diarrhœa and enteritis (under 2 years).	Total.	Annual rate per 1000 persons living.

PERICARDIAL FRICTION AND CORONARY THROMBOSIS.

To the Editor of THE LANCET.

SIR,—In an annotation in THE LANCET of June 5th (p. 1232) you call attention to transient pericardial friction as a sign of coronary thrombosis, and to six cases reported by Dr. L. W. Gorham, of Albany. You speak of this condition as "almost unrecognised," and "not mentioned in the text-books." Dr. Gorham's cases are very interesting, but it is hardly true that patches of pericarditis at the sites of coronary thrombosis have not been fully recognised in England. If your readers will do me the honour to turn to my work on "Diseases of the Arteries," Vol. II., pp. 460ff, they will find these events discussed at some length. The occasional relation to angina pectoris also is indicated, and suggestions made to explain the occurrence of anginal pains in some cases in which, with coronary thrombosis, there is no pericarditis.

I admit I have not had the good fortune to meet with the considerable pathological proofs which have fallen to the lot of Dr. Gorham, but do not let us in England appear ignorant of the subject.

I am, Sir, yours faithfully,

Cambridge, June 12th, 1920. CLIFFORD ALLBUTT.

WAR ŒDEMA AND EPIDEMIC DROPSY.

To the Editor of THE LANCET.

SIR,—I have read the letter by Dr. J. A. Nixon in THE LANCET of April 24th on the subject of War Œdema and Epidemic Dropsy. I do not consider that any confusion will result from Dr. A. D. Bigland's valuable article on "Œdema as a Symptom in So-called Food-deficiency Diseases"; on the contrary, it gives a very clear and complete account of our present knowledge of the subject. Indeed, Dr. Nixon himself somewhat obscures the issues when he states that "the disease called by Macleod epidemic dropsy, with its itching, burning, and erythema or urticaria which preceded or accompanied the anasarca, was probably ankylostomiasis." In the course of my investigations on the Ætiology of Epidemic Dropsy in India, published in the Scientific Memoirs of the Government of India, Nos. 45 and 49, I obtained no evidence that the disease was ankylostomiasis; on the other hand, the results of my researches pointed definitely to epidemic dropsy, as seen by me in Calcutta and other places in India, being a form of food-deficiency disease. The statement that "this dropsical disease was by no means confined to the impoverished and sickly" proves nothing, because it is necessary to remember in this relation that the diet of well-to-do people, although expensive, may be, from the modern view-point, nutritionally deficient; thus highly polished rice, which is consumed by the richer classes in India, is more costly than the coarser varieties of rice, but, as is now well known, the former is more deficient in vitamines than the latter.

I am, Sir, yours faithfully,

E. D. W. GREIG.

Pasteur Institute of India, Kasauli, May 21st, 1920.

THE STANDARDISATION OF COLOUR PERCEPTION.

To the Editor of THE LANCET.

SIR,—I have read Mr. Herbert Parsons's letter in THE LANCET and have to thank Mr. Percy Dunn for his reply in your last issue. I shall welcome Mr. Parsons's attack on my views, but I hope it will not appear in a lay paper. The editors of different lay papers have received communications depreciating my work, and though none of these have been inserted, in any case I wish to reply through a scientific medium. Mr. Parsons should be the last person to belittle my work, as he is now using my methods after having opposed them long and fiercely. In 1889, as member of the International Code of Signals Committee, I constructed the lantern, which is now the official test of the navy, for the Board of Trade. Opinion at that time, however, was in favour of the wool test and the non-use of colour names. A special committee of the Royal Society was appointed which recommended the wool test. This discredited me for many years. The wool test is now obsolete, as more than 50 per cent. of dangerously colour-blind persons can pass it and a very large percentage of normal-sighted are rejected. Yet in 1912, in a new edition of his book, Mr. Parsons wrote:—

> "The fundamental axiom in colour testing is that no importance should be attached to the naming of colours...... Holmgren's wools are sufficiently good."

This statement was made when nearly the whole world had recognised the inefficiency of the wool test and the necessity for the use of colour names. In the Ophthalmological Section at the British Medical Association meeting at Brighton, 1913, a resolution was proposed condemning the wool test. Mr. Parsons was the sole member who voted against the resolution.

I have for many years whenever a foreign scientist interested in vision has visited me, and has told me that he was going on to one of my opponents, requested him to let me know of any objection made so that I could answer it. In every case on returning he has told me that certain particular people, the same in every case, had nothing good to say of my work, but were quite unable to point out any fact or deduction which was wrong. I naturally look forward to having something to which I can reply.

I am, Sir, yours faithfully,

London, June 12th, 1920. F. W. EDRIDGE-GREEN.

To the Editor of THE LANCET.

SIR,—Mr. Percy Dunn's saeva indignatio has led him into making some rhetorical exaggerations. "The 100 per cent. of those who have failed to prove that any of his statements are wrong" is one such. The following is an example refuting this pronouncement. Lord Rayleigh stated that he could distinguish between the wave-lengths included in a monochromatic division to the extent of discriminating between the colours of the two D lines.[1] Dr. Edridge-Green traversed this statement and attributed the error to "the admixture of small quantities of white and coloured light and to certain physiological influences."[2] Dr. Wm. Watson conclusively disproved any such influence of admixture with white light,[3] and found that 14 observers gave the following mean values with sodium light: width of monochromatic patch = 4·5 $\mu\mu$; difference in wave-length easily detected as a change in hue = 1·4 $\mu\mu$. It is further to be remembered that there is a wealth of argument against some of Dr. Edridge-Green's theories, so that opponents may not have felt it necessary to controvert them. Thus, I know of, at any rate, one scientist whom Dr. Edridge-Green claims as a strong adherent, who yet dissents entirely from his theory as to the action of the visual purple.

With regard to the "prejudicial attitude" assumed against Dr. Edridge-Green, this, if true—and I believe it originated in events occurring before I became actively interested in the subject—was a personal matter and does not affect the scientific arguments. I have yet to be convinced that the Royal Society was so influenced as to commit the worst crime against science—that of perverting scientific truth from ulterior motives.

I have already said that I consider Dr. Edridge-Green's colour perception lantern good, and it is not surprising, for reasons stated in my last letter among others, that various Government departments have adopted it. I fail to follow Mr. Dunn's arguments that a test requiring skilled knowledge is better than one more "fool-proof." Would a test for visual acuity be better if a high degree of special training were required to use it? That depends, I take it, upon the degree of accuracy required for the given purpose. I must confess that I cannot interpret the innuendo contained in the last sentence of Mr. Dunn's letter.

POISONING BY EXHAUST GAS.

To the Editor of THE LANCET.

SIR,—On May 8th I was called to see two children, aged respectively 11 and 6 years, with the following history:—

They started to drive 10½ miles in a half-covered business car, open to the front, which contained groceries. They were inside the car, the mother sitting on the front seat by the driver. When they had driven 10 miles the mother heard one of the children crying; she got down and found the younger child delirious, with her head fallen forward; the elder child was trying to comfort the younger one. She got them out of the car, when the elder child staggered about the road and fell down. She put them on the seat by the driver and came on to Lichfield.

I found them both in a state of semi-collapse. Pulse small and feeble. Faces pale. No cyanosis. They were constantly sick, which ultimately became bilious in character. In the evening the elder child complained of headache. The younger child was better, but developed a croupy cough during the night, with no physical signs and no infection of the fauces. The next day they were better and taking food, but the elder child was feeble and wanted to lie down when she was dressed. They went home in the afternoon, and I am told that the cough in the younger child continued for three or four days. They ultimately got quite well.

No. 3 spirit was being used in the car, the exhaust pipe of which only reached half-way to the bottom of the car. What was the gas which caused these symptoms? Does No. 3 spirit contain benzol, which, I believe, contains toluol and xylol? Was it a case of toluol poisoning?—I am, Sir, yours faithfully,

Lichfield, Staffordshire. GEORGE W. HOMAN.

⁂ Cases of serious disturbance to health by the inhalation of light hydrocarbons, used as propellants of motor vehicles, are well known, but the above letter raises the question whether, in the circumstances described, the poisoning was due to leakage of hydrocarbons or to the products of their complete or incomplete combustion. The symptoms described are in accord with those produced by benzene inhalation (or petrol itself), and toluene vapours (methyl-benzene) act much in the same way as benzene. References to similar occurrences will be found in issues of THE LANCET dated April 5th, 1913 (p. 975), Jan. 27th, 1917 (p. 161), and Oct. 12th, 1918 (p. 494).—ED. L.

THE "TOXICITY" OF METHYLENE-BLUE.

To the Editor of THE LANCET.

SIR,—In your issue of Feb. 17th, 1917, you were good enough to insert a short letter on the above subject. Since then, while employed as consultant in malaria for the Scottish Command, I have been able to make more extended researches on the value of this remedy in the treatment of malaria and other affections, and also especially to note the presence or absence of toxic symptoms.

The total quantity of methylene-blue used in one hospital alone (the Edinburgh War Hospital, Bangour) amounted to over two pounds in weight, representing about 5000 doses of 3 gr. each. The number of malaria cases treated numbered over 3000. It may therefore justly be claimed that conclusions reached from observations on such a wide base are worthy of consideration.

I wish to combat the idea that methylene-blue possesses toxic properties, and the following few facts regarding the results obtained by its use may be of interest; a fuller statement on these points will be published later.

The drug was chiefly used in the treatment of malaria and flagellate infections of the intestine. In acute malarial attacks it was found that though in many cases favourable results were obtained, the efficacy of methylene-blue in cutting short attacks was distinctly inferior to quinine. On the other hand, it frequently proved a valuable remedy in preventing relapses, especially in cases where quinine, administered by the mouth or by intramuscular and intravenous injections, had signally failed.

The results obtained in flagellate infections were fairly good, though often unsatisfactory.

Regarding "toxicity," although some of the patients received over 400 gr. in a course of treatment extending over several weeks, beyond occasional complaints of slight bladder irritation no troublesome symptoms were manifested which could be attributed to the use of the drug. It may therefore be accepted that in methylene-blue we possess a remedy of great value; and that, provided a pure supply is obtainable, it may be freely used without fear of "toxic" symptoms resulting. I am, Sir, yours faithfully,

Edinburgh, June 10th, 1920. D. G. MARSHALL.

THE SURGICAL TREATMENT OF PROLAPSE OF THE UTERUS AND VAGINA.

To the Editor of THE LANCET.

SIR,—I do not think it is my business to attempt to disperse the fog that enshrouds the thoughts and impressions of Mr. R. H. Paramore. *That he lacks lucidity* and is, therefore, unsuited to teach was amply manifest in his first letter. I ask you to imagine, Sir, a medical student endeavouring to understand and assimilate what, no doubt, Mr. Paramore considered words of wisdom. Several intelligent practitioners have assured me that they obtained no glimmering of light after reading his letter through more than once. I have never before myself been accused of nebulosity, and on the present occasion Mr. Paramore would have been well advised if he had avoided the cheap form of argument that is abhorred by every school-boy. However, my only concern in taking notice of his first letter was to prevent those who might read his remarks imagining that the statements concerning myself were correct, for, as Mr. Paramore says, criticism in THE LANCET receives wide publicity.

It is necessary for me once more to controvert the intentional inaccuracies of Mr. Paramore, who, in spite of being exposed for similar inaccuracies in his first letter, in your issue of June 12th, not only attributes to me more views and statements I have never held or made, but also makes two definite aspersions: one is that I do not know the meaning of the word "floor": the second implies that I do not understand the significance of the adjective "congenital." I am afraid I must ignore any further puerile insinuations of this sort until I have some evidence that Mr. Paramore has taken the trouble to read my book, "The Principles of Gynæcology," third edition, if the abstract of my lecture in THE LANCET, which should be read as stated in conjunction with this work, does not make everything clear to him. In my book he will discover the term "congenital" qualified on p. 212 and elsewhere, as it was qualified in my lecture, and he will find the pelvic floor discussed on p. 47, and in my lecture I described, for want of a better name, as I stated definitely at the time, an operation for "the reconstruction of the posterior segment of *the peritoneal aspect* of the pelvic floor"—indeed, I asked for a better description of the procedure.

We must have lucidity and honesty, and until we get them there will be much diverse teaching in regard to the surgical treatment of prolapse, which, after all, was the subject of my lecture. Had Mr. Paramore heard some of the remarks I have heard from doctors and patients regarding so-called cures for prolapse he would have realised that facts and figures *are* important. (Honesty may be assumed until the contrary has been proved, in accordance with British traditions of justice.) Moreover, good operations are the result of good reasoning, whatever may be Mr. Paramore's subsequent interpretations of them, and technique is of considerable importance. In my lecture I was speaking to a large number of surgeons of experience who could correctly interpret the reasons for my adopting the procedures advocated without my treating my audience to a discourse on elementary anatomy I have, consequently, suggested that Mr Paramore should publish his own figures and methods, if he has any worthy of publication In regard to figures there is a general idea that Mr Paramore has himself done comparatively few operations for prolapse, and this is supported by his statement that he has performed only twice the interposition operation, although he approves of it If this idea be erroneous it would be well for him to dispel it As to methods, if Mr Paramore has any new procedure why is he so secretive about it? I must leave your readers to draw their own conclusions Meanwhile, it is surely a little presumptuous of Mr Paramore to attempt to interpret procedures thought out and introduced by others, some of which he has never seen and concerning the object of which he has not even troubled to inquire

I am afraid I have written plainly it is time someone did Critics who adopt the methods to which I have referred must be checked Even abuse is much preferable to perversions of one's views and statements

I am, Sir, yours faithfully,

Liverpool, June 13th 1920 W BLAIR BELL

THE IMPORTANCE OF IMMEDIATE SELF DISINFECTION.

To the Editor of THE LANCET

SIR,—Neither Lord Willoughby de Broke nor the society over which he presides believes that the establishment of disinfectant centres would be of much value in reducing venereal disease, and during his speech on June 3rd Lord Willoughby de Broke brought forward powerful arguments against the practicability of ablution centres By inference the report in your issue of June 12th suggests that Lord Willoughby de Broke is in favour of the establishment of disinfectant centres, which is not the case, and I write lest a misunderstanding may arise as to the aims and objects of this society, which are to instruct the public as to (*a*) the vital importance of self disinfection at the time of exposure to risk as a preventive of venereal disease, and (*b*) the methods of application

I am, Sir, yours faithfully,
H WANSEY BAYLY,
Hon Sec Society for the Prevention of Venereal Disease
143 Harley street W 1 June 12th 1920

AGE AND VENEREAL INFECTION

To the Editor of THE LANCET

SIR,—At the instigation of Colonel L W Harrison last year I made a private inquiry into the sex history of 600 consecutive V D cases, chiefly with a view to determining the infection exposure ratio, this worked out at 1 15 6 Dr G G Johnstone observes in THE LANCET of June 12th that there is a sharply defined maximum at the age of 18, when illicit coitus begins I found that 469 out of the above series of 600 stated that their first sexual intercourse took place between the ages of 17 and 21 It is an important sociological fact, hardly needing to be proved by statistics, that normal sexual man is most prone to indulge in pseudo romance during the latter period of exuberant adolescence, when ideals may be in a transition phase

My predecessor, Captain W Craik, in statistics carefully kept over a series of several thousand cases, found that 86 per cent (I quote his figures from memory) were infected by "amateurs" Also, that 24 per cent of the men were teetotallers and few claimed to be drunk at the time —I am, Sir, yours faithfully,

JOHN DONALD, M D, B Sc, D P H,
Major
De Montfort square Leicester June 13th 1920

PERIOD OF SERVICE FOR GRATUITY TO R A M C CAPTAINS —A Royal Warrant states that captains of the R A M C who receive a permanent commission in this corps subsequent to May 25th, 1920 must complete eight and a half years total commissioned service in order to qualify for the gratuity of £1000 payable to retiring officers

Medical News.

UNIVERSITY OF CAMBRIDGE —The dates for the next examination for the Diploma of Psychological Medicine have been fixed as follows for Part I Oct 13th, 14th, and 15th, for Part II, Dec 1st, 2nd, and 3rd The examination for Part I will be held in Cambridge, that for Part II in London Courses of instruction for both parts will be held in Cambridge from July 19th to August 21st, and will include lectures and demonstrations For Part I Dr C R A Thacker, Anatomy and Physiology of the Nervous System, Dr J P Lowson, Psychology For Part II Dr E Prideaux, Psychopathology, Dr M A Archdale, Diagnosis Prognosis, and Treatment of Mental Disorders The fee for the full course is 10 guineas, the course for either part may be taken separately at a fee of 5 guineas Entries should be sent to Dr E D Adrian, Trinity College Cambridge, from whom further information may be obtained

ROYAL COLLEGE OF SURGEONS OF ENGLAND —An ordinary meeting of the Council was held on June 10th at the College, Sir George Makins presiding A report was read from the Board of Examiners in Anatomy and Physiology for the Fellowship stating that at the examination concluded on May 15th 168 candidates were examined including 52 admitted under the special war conditions of whom 38 were successful, and 116 admitted under the ordinary conditions, of whom 36 were successful —A report was read from the Court of Examiners respecting candidates found qualified for the Diploma of Fellow, and diplomas were granted to 39 candidates mentioned in this report The names will be published next week, as well as those of the candidates found qualified for the Licence in Dental Surgery

The following were elected Members of the Board of Examiners in Anatomy and Physiology for the Fellowship for the ensuing year —

Anatomy —J Ernest Frazer F R C S W F Haslam F R C S Gordon Taylor, O B E F R C S A Ralph Thompson F R C S

Physiology —F A Bainbridge M D J B Leathes M D H W Lyle M D A Rendle Short M D

The following were elected Examiners under the Conjoint Examining Board in England for the ensuing year —

Elementary Biology —J P Hill D Sc T W Shore M D

Anatomy —D Hepburn C M G C M Edin, F G Parsons F R C S Arthur Thomson F R C S

Physiology —G A Buckmaster M D H E Roaf M D

Midwifery —J S Fairbairn F R C S Cuthbert Lockyer, F R C S C D Robinson M D G F Darwall Smith F R C S

Public Health —Sir F W Andrewes M D F N Kay Menzies M D

Tropical Medicine and Hygiene —G C Lowe M D H B G Newham M D

The President reported that the five surgeons who were elected honorary Fellows of the College on Feb 12th last would attend to receive their diplomas on Thursday July 8th next, and that it was proposed that the diplomas should be presented to them at 7 30 P M on the same day and that they should afterwards be entertained to dinner in the College by the Council

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW —At the monthly meeting of the Faculty, held on June 7th the following were admitted (after examination) as Fellows —

Norman Stewart Bruce James Alphonsus Conway John Norman Cruickshank John Gracie Stuart Spence Meighan Joseph Hume Patterson Daniel M Kinlay Reid William Robertson Snodgrass Ian Dishart Suttie and Gavin Young

ROYAL COLLEGE OF SURGEONS IN IRELAND —The annual election of President and Vice President and Council of the Royal College of Surgeons in Ireland held last week resulted in the election of Mr Edward H Taylor, the outgoing Vice President as President and of Sir William I de C Wheeler as Vice President The latter was opposed by Mr R C B Maunsell, and considerable interest was taken in the contest The new president Mr Edward Taylor has been since 1916 Regius Professor of Surgery in the University of Dublin and has been for many years surgeon to Sir Patrick Dun's Hospital Prior to his appointment as Regius professor he was for some ten years professor of surgery in Trinity College He is the author of well known text books on Applied Anatomy and on Operative Surgery Sir William Wheeler, who succeeds Mr Taylor as vice president is surgeon to Mercer's Hospital and to the Orthopædic Centre for Pensioners He was a consulting surgeon to H M Forces in Ireland during the war, and was recently awarded a knighthood in recognition of his services He has contributed many surgical articles to the current literature and he is a regular contributor to the *Medical Annual*

London Medical Exhibition.—The tenth exhibition is arranged to be held in the Central Hall, Westminster, S.W., on Oct. 4th, 5th, 6th, 7th, and 8th next.

The Cavendish Lecture will be delivered before the West London Medico-Chirurgical Society by Professor C. S. Sherrington on Friday next, June 25th, at 8.15 P.M., at the Kensington Town Hall. The subject taken is "Posture." The lecture will be preceded by a reception at 7.45 P.M. There will be medical and surgical exhibits.

Anatomical Society of Great Britain and Ireland.—The annual summer meeting of this society will be held at Cambridge on Friday and Saturday, July 2nd and 3rd, following upon the meeting of the British Medical Association at the same place. The programme promises to be full of interest and importance. Several papers on the Morphology and Development of the Central Nervous System have been promised, while such themes as the "Structure of the Earliest Land Vertebrates," "Partial Transposition of the Mesogastric Viscera," and "Avian Structure as Bearing upon Problems of Bird Migration" will provide fertile fields for discussion.

Royal Society of Medicine.—The annual election of officers and Council for the ensuing year will be held at the annual general meeting of Fellows at the Society's House on Wednesday, July 7th, at 5 P.M. The Council has nominated the following:—

As President: Sir John Bland-Sutton, F.R.C.S.

As Honorary Treasurers: William Pasteur, C.B., C.M.G., M.D.; C. H. Fagge, M.S.

As Honorary Librarians: Raymond Crawfurd, M.D.; Walter G. Spencer, M.S.

As Honorary Secretaries: A. M. H. Gray, C.B.E., M.D.; W. Girling Ball, F.R.C.S.

Other Members of Council: Lady Barrett, C.B.E., M.D.; J. Charlton Briscoe, M.D.; J. F. Gordon Dill, M.D.; John Fawcett, M.D.; J. Herbert Fisher, F.R.C.S.; Robert Hutchison, M.D.; Herbert S. Pendlebury, F.R.C.S.; Sir D'Arcy Power, K.B.E., F.R.C.S.; Guy E. M. Wood, M.D.

Section of Laryngology.

The second annual Summer Congress will be held at the Royal Society of Medicine, 1, Wimpole-street, London, W., on June 24th and 25th. An exhibition of pathological specimens and drawings will be held from 10 A.M. to 6 P.M. during the two days of the Congress, and there will also be an exhibition of surgical instruments and drugs from 2 P.M. on the 24th to 1 P.M. on the 25th. On Thursday, June 24th, at 2.30 P.M., a series of papers on cancer of the throat will be read by Sir Charters Symonds, Mr. Wilfred Trotter, Dr. Logan Turner, Mr. Edward D. D. Davis, and Sir StClair Thomson. On Friday, June 25th, at 10 A.M., miscellaneous communications will be given by various members, including Dr. A. Brown Kelly, Sir William Milligan, Dr. Watson-Williams, Mr. Lawson Whale, Dr. Irwin Moore, and Mr. W. M. Mollison. At the afternoon session demonstrations will be given by Dr. Llewelyn Powell, Dr. Felix Rood, Dr. F. E. Shipway, Dr. H. E. G. Boyle, Dr. E. P. Cumberbatch, Mr. Hayward Pinch, Mr. Layton, Mr. Norman Patterson, and Dr. Irwin Moore. On the first day of the meeting a dinner will be held at the Café Royal at 7.30 P.M. Applications for tickets (12*s.* 6*d.*) should reach one of the secretaries, Dr. Irwin Moore, 30A, Wimpole-street, W.1, or Charles W. Hope, 22, Queen Anne-street, W.1, not later than Monday, June 21st.

The Treatment of Tuberculosis in Belfast.—Dr. A. Trimble, as medical adviser to the Belfast Insurance Committee, has just presented his report dealing with the year 1919. The death-rate from pulmonary tuberculosis in Belfast, which was 2·7 per 1000 in 1918, has fallen to 2·1 in 1919. Of the total of 2377 persons examined 887 (37 per cent.), were insured and exempt persons examined on behalf of the Committee, the remainder, 1490 (62·7 per cent.) being non-insured persons examined under the corporation scheme. Of those examined, 8 per cent. were found to be tuberculous or suspect. Dr. Trimble says that while the large number of females employed industrially in Belfast accounts in some measure for the high tuberculosis mortality amongst them as compared with females in large English towns, yet the higher rate of tuberculosis amongst females in the rest of Ireland over the rate amongst males requires some other explanation. As to sanatorium treatment, he thinks it is the best form of treatment in the incipient state of the disease, "but the continuance of improvement largely depends on the patient after leaving the sanatorium attending the dispensary for further treatment," for in advanced cases the sanatorium method can only mitigate the suffering of the patient. Of 1840 new cases treated, 24 were "apparently cured," while in 100 the disease was "quiescent," 178 were greatly improved, 791 improved, 630 in statu quo, and 117 worse. Reference is made to the serious effect of overcrowding owing to the housing problem. The report is, in existing circumstances, depressing.

Middlesex Panel Committee: Presentation to Dr. H. B. Brackenbury.—At the monthly meeting of the Middlesex Panel Committee on June 10th Dr. Brackenbury, who has acted as chairman of the Committee since its inception in 1914, was presented by the members of the Committee with a solid silver coffee pot, sugar bowl, and cream jug. The presentation was made by Dr. C. F. T. Scott, vice-chairman of the Committee, in a felicitous speech in which he attributed the success of the Committee to Dr. Brackenbury's able chairmanship and statesmanlike qualities. Dr. Brackenbury, who was enthusiastically received, thanked the Committee for their kindness, stating that in all his public work he had been governed by the desire to serve the best interests of his fellow insurance practitioners and to promote the public welfare.

Reference was made in the course of the proceedings to the fact that Dr. Brackenbury has been chosen as Liberal candidate for East Walthamstow.

Proposed Amalgamation of Bristol Hospitals.—At a meeting of the governors of the Bristol General Hospital, held on June 14th, it was decided to continue the discussion of the scheme of hospital amalgamation that has been proposed. This scheme already has the support of several of the Bristol institutions, but it is held by the committee of the General Hospital to need considerable modification if their institution is to enter the proposed amalgamation.

Death of Dr. Francis McLaughlin.—The death is announced of a leading Londonderry medical practitioner, Dr. Francis McLaughlin, which occurred at his residence in that city on June 9th from pneumonia, contracted, it is believed, from a chill during a long drive to see a patient. The deceased, who studied in Queen's College, Galway, where he was a scholar, graduated M.D. with honours in the Royal University of Ireland in 1881. Starting practice in Londonderry, he soon acquired a large clientèle, and was extremely popular with all classes. He was a J.P. for the city of Londonderry, where, on the morning of his decease (so little was his death anticipated), the recorder appointed him as medical referee in a compensation claim.

Manchester Schools for Mothers.—The annual report of the Manchester group of "schools for mothers" has recently been issued. The average number of children attending the various welfare centres each week was 1440, as compared with 980 in 1918 and 803 in 1917. During the year two new centres with antenatal clinics were formed by the Public Health Department. The experience of infant welfare centres has shown clearly that unguided instinct can no longer be regarded as the only requisite for the successful rearing of children, and consequently schools for mothers have been established in various centres. The mothers are taught how to promote the comfort of their children in the matter of suitable food, clothing, and general hygiene. A considerable part of the expenses of the schools for mothers is borne by the corporation, through the association of these schools with the Public Health Department, but even with this assistance the cost is not being met, and additional public support is required.

Royal Society of Tropical Medicine and Hygiene.—His Majesty the King has been graciously pleased to command that the Society of Tropical Medicine and Hygiene shall henceforth be known as "The Royal Society of Tropical Medicine and Hygiene." The formation of a society to promote the study of the diseases and hygiene of warm climates was considered by a number of interested persons in January, 1907, at a meeting at the Colonial Office. In due course the society was constituted, with Sir Patrick Manson as President and Major Ronald Ross as Vice-President. The first ordinary meeting was held in June, 1907, and since that date, except during and subsequent to the war when the number of meetings was reduced, eight meetings have been held yearly and 13 volumes of Transactions have been published. The meetings have been well attended, the number of Fellows present rarely falling below 50; and on these occasions Fellows and their friends have the opportunity of exchanging views with workers from all parts of the world. At the end of the first year there were 186 Fellows, and the number is now 660. In the last 12 months 175 Fellows have been elected. From the first the society has been open to all persons interested in its objects, whether medical men or not, who are approved by the Council, and many veterinary practitioners are included amongst its Fellows. The Presidents in succession to Sir Patrick Manson have been Sir Ronald Ross, Sir William Leishman, Sir Havelock Charles, the late Dr. F. M. Sandwith, and Sir David Bruce. The President is now Professor W. J. Simpson. The subscription to the society is 1 guinea, but a rise to 1½ guineas is under consideration. The society's headquarters are at 11, Chandos-street, Cavendish-square, London, W.

A Royal Charter has been granted to the Incorporated Society of Trained Masseuses

OPHTHALMIA NEONATORUM IN BOMBAY —The Blind Relief Association of Bombay is embarking upon a propaganda campaign for reducing the incidence of *infantile ophthalmia* It has published a pamphlet describing preventive measures to be taken immediately on the birth of a child Help in carrying out the precautions is to be obtained from existing local bodies, such as the Sanitary Association and the Health Visitors and Infant Welfare Committee

NORTH EAST LONDON POST GRADUATE COLLEGE VACATION COURSE —A special post graduate course will be held at the Prince of Wales's General Hospital, Tottenham, N, from Monday, July 19th, to Saturday, July 31st, inclusive It will comprise morning demonstrations on clinical methods, including laboratory methods of the examination of cases, and in the afternoons demonstrations on groups of illustrative cases general hospital practice in the various departments, and clinical lectures and consultations On Saturday morning clinical demonstrations will be given in affiliated special hospitals The fee for the course is 3 guineas, or 2 guineas for either week Further particulars, with syllabus as soon as it is ready, may be obtained from the Dean, at the hospital, or at 19a, Cavendish square, W 1

Parliamentary Intelligence.

HOUSE OF LORDS

THURSDAY, JUNE 10TH

The Census Bill

Viscount ASTOR, in moving the second reading of the Census Bill, said that hitherto a separate Act of Parliament had been passed for each census It was proposed that this Bill should be a perpetual Census Bill, empowering His Majesty from time to time, by Order in Council, to direct that a census should be taken for Great Britain or for any part of Great Britain Power was taken to make a census every five years instead of every ten years, so as to secure greater accuracy for the fundamental figures as to population By Clause 6 it was provided that a local census might be made subject to the approval of the Ministry of Health —The Bill was read a second time

HOUSE OF COMMONS

WEDNESDAY, JUNE 9TH

New Indian Army Pension Rates

Mr AUBREY HERBERT asked the Secretary for India whether, in view of the anxiety and uncertainty in the minds of many Indian Army officers who were contemplating retiring owing to the changed conditions of service in India, but could not do so until the new pension rates were published, he could now state when these rates would be published —Lieutenant Colonel ASSHETON POWNALL asked the Secretary for India whether the new scale of pensions for retired officers of the Indian Army had yet been approved —Mr MONTAGU replied A communique giving particulars of the new scale of pensions for officers of the Indian Army and Indian Medical Service was sent to the press on June 3rd and published the following day

Extra Nourishment for Tuberculous Persons

Mr CHARLES EDWARDS asked the Minister of Health whether local War Pensions Committees were authorised to make provision for extra nourishment for ex Service men in sanatoriums or at home who were suffering from tuberculosis and in need of special diet, and if he would make provision for similar grants to be made to insured persons who were suffering from the same cause —Dr ADDISON replied I understand that this provision is made in the case of ex Service men suffering from tuberculosis who are under treatment at home, and Insurance Committees are empowered to make similar provision for other insured persons so far as the funds available for sanatorium benefit, after providing for other calls upon these funds, will allow The question of providing "extra" nourishment for patients under treatment in sanatoriums is one which scarcely arises in practice These patients receive the dietary provided by the institution, which is specially adapted to the needs of tuberculous patients and may be varied at the discretion of the medical superintendent to meet the special needs of individual cases

Poor law Officers and Reform of the Poor law

Mr BRIANT asked the Minister of Health if he would withhold his assent to any scheme of a board of guardians for the reorganisation of its institutions or services prior to the introduction of a measure dealing with the Poor law system as a whole until he was satisfied that amicable arrangements had been made with the officers concerned, and if, in the event of Poor law officers suffering monetary loss owing to a transfer of a portion of their duties to other authorities or offices he would satisfy himself that the guardians had made adequate compensation for such loss as might be sustained by them —Dr ADDISON replied It is already the practice to give full consideration to the position of any officers affected by a reorganisation of services

Dental Legislation

Mr RAFFAN asked the Minister of Health if he could now state when it was proposed to introduce legislation for the purpose of carrying out the recommendations of the Select Committee on the Dentists Act, 1878 —Lieutenant Colonel HURST asked the Minister of Health whether he was now able to make a statement as to the prospects of legislation this session in respect of the registration of dentists and dental practitioners —Dr ADDISON replied I regret that, owing to the pressure of other legislation, the draft of this Bill is not yet completed, and I am unable to say when it will be introduced, though I hope it will be ready shortly

Elimination of Slum Areas

Mr L'ESTRANGE MALONE asked the Minister of Health whether the powers given to local authorities under the Housing and Town planning Act were sufficient to enable them to eliminate slum areas, and, if so, what steps were being taken to enforce these provisions —Dr ADDISON replied I think that the powers under the Housing Acts are generally sufficient, but, as the honourable Member will appreciate, it is scarcely practicable to deal on a large scale with slum areas, or to undertake the demolition of houses, until much more has been done to meet the prevailing shortage of houses Local authorities have been requested to proceed with the survey of the unhealthy areas in their districts and with the preparation of schemes in the most urgent cases I will send the honourable Member a copy of the manual on the subject which has been issued

Mr MALONE asked the Minister of Health if he would state the extent of the slum areas, given in acreage number of houses or number of rooms, which had been condemned as unfit for habitation since the creation of the Ministry of Health, the number of occupants so affected, and the numbers for whom new accommodation had been erected —Dr ADDISON replied Since the creation of the Ministry of Health local authorities have submitted for confirmation improvement schemes for areas comprising 10¾ acres and 494 houses, occupied by 2938 persons of the working classes New housing accommodation is proposed to be provided in connexion with these schemes for 2820 persons These schemes are now being considered by my Department —Mr RAFFAN Have any of these schemes been confirmed?—Dr ADDISON Several of them are being confirmed, but I cannot say how many We do not propose to deal with them until more of the existing shortage is dealt with —Mr MALONE Is not an acreage of 10¾ a very small percentage indeed of the slum areas of our industrial towns?—Dr ADDISON Of course it is, but schemes which are before us relate to vast areas of our slums We cannot confirm orders until there is some prospect of sufficient additional accommodation to justify the demolition of these houses We must do these things by stages

Treatment Allowances of Disabled Men

Mr ALFRED DAVIES asked the Minister of Pensions whether treatment allowances could be withdrawn from a disabled man who, owing to his disability, was unable to follow his present occupation, and who was receiving out patient treatment but was certified fit for easy light work, or whether he was entitled to receive full treatment allowances pending his return to his own employment —Major TRYON (Parliamentary Secretary to the Ministry of Pensions) replied For cases of out patient treatment special provision is made by Article 6 of the Royal Warrant in the form of an allowance for loss of remunerative time Full allowances at the maximum rate of pension (to which the honourable Member appears to refer) are only payable where a pensioner who is certified to need a course of treatment is judged to be unable in consequence to provide for his own support and that of his family The question whether in any given case the time occupied in or other circumstances attending the course of treatment prescribed are such as to entitle the man to the maximum allowances must be decided on the facts of the case

Medical Men and Motor car Rebate

Mr RAMSDEN asked the Chancellor of the Exchequer whether, in the event of any rebate being granted to medical men whose work necessitates them running a motor car, the same privilege will be extended to county coroners —Mr NEAL (Parliamentary Secretary to the Ministry of Transport) replied As I stated on June 3rd, the Minister of Transport is unable to recommend a rebate of the proposed taxation of motor vehicles in the case of those used by medical practitioners

THURSDAY, JUNE 10TH.

DANGEROUS DRUGS BILL.

Major **BAIRD** (Under Secretary to the Home Office), in moving the second reading of the Dangerous Drugs Bill, said that it gave effect to the International Opium Convention, signed at The Hague on Jan. 23rd, 1912. The purpose of the Convention was to bring under control throughout the world the traffic in opium and cocaine, and preparations derived from them, and to restrict their use to medical and other legitimate purposes. The Convention was signed on behalf of all the Powers represented, with the exception of Turkey and Serbia. Some of the countries, including Germany, failed to ratify the Convention before the outbreak of war, and it was never brought into operation. During the war Great Britain found it necessary to take action on her own account owing firstly to the spread of the cocaine habit, and secondly to the extensive smuggling of opium carried on in the East, which caused trouble and delay to our merchant shipping in connexion with China. Therefore, a Regulation, No. 40B, was made under the Defence of the Realm Act, which enabled them to control the manufacture, sale, and distribution of cocaine; and a proclamation was issued, under the Customs Consolidation Act, to prohibit the import of cocaine or opium except under license of the Secretary of State. Those measures did not prove altogether successful, largely owing to the difficulty of controlling smuggling in the case of an article which could be brought in in such small quantities and so easily sold as opium. They believed that the only effective control would come by international coöperation. The Allied Powers attached so much importance to this question that the ratification of the International Convention was made one of the conditions of peace and was embodied in Article 295 of the Peace Treaty, which bound the contracting parties to bring the Convention into force and to enact the necessary legislation within 12 months of the coming into force of the Treaty. It became doubly important that they should have the power which this Bill would confer if it became an Act, because of the impending abrogation of the Defence of the Realm Regulations. The Bill was limited to carrying out the Convention except in one respect—namely, in Clause 8, Subsection (2), where powers were asked for to extend provisions not only to the derivatives of morphine and cocaine, but to any other alkaloid of opium, and any other drug of any kind which was likely to produce the same injurious effects. Another reason why they were anxious to have the powers which the Bill conferred upon them was that their representatives in China and Japan had repeatedly referred to the disastrous effects on the traffic which was being carried on with China in morphia and cocaine to a very large extent, and both China and Japan were signatories to the Convention.

Lieutenant-Commander **KENWORTHY**: When it is passed will this Bill be able to stop the whole of this great trade in morphia?—Major **BAIRD** said it was doubtful whether it would stop the whole of it, but the Bill embodied the best means which commended themselves to those who represented these 42 Powers at the International Convention, and it represented the results of their labours and their recommendations. It might not be perfect, but it was a great step in advance, and they hoped that if they got these powers they would be able largely to assist our Allies in Japan and our friends in China to deal with this very important and pernicious matter. Naturally, a big measure of this kind affected the interests of large bodies of their fellow countrymen, and the Pharmaceutical Society had made representations. Both with regard to their representations and others which they had had from the wholesale dealers they hoped to be able to meet them. As regarded the Pharmaceutical Society, they had already had an opportunity of considering the points which they advanced, and with one exception he hoped in Committee it would be possible to accept amendments which would meet their views. As regarded the wholesale dealers, they expressed a desire to put their views before the Home Secretary, but only so recently as a day or two ago, and therefore it had not been possible to meet them and discuss the question, but with regard to both these important bodies they were most ready to listen to any representations which would enable them to devise some amendments which would alleviate any legitimate hardships without weakening the force of the measure to which they attached very great importance. The details of the Bill were of a very technical character. Everyone was imbued with the desire to restrict the misuse of this most valuable drug and to collaborate with other countries in reducing its uses to legitimate and proper preparations, and seeing that the Bill embodies the recommendations of this very competent body of men, representative of practically all the nations who assembled at The Hague in 1912, he hoped the House would be content to give them the second reading without prolonged discussion.

The International Aspect.

Dr. D. **MURRAY** congratulated the Home Secretary on taking up the international aspect of this question. The history of this country in connexion with the drug habit all over the world and in connexion with the opium traffic had been one of the most disgraceful pages in our history, and one which we could never look back upon without a sense of shame. It was a hopeful augury for the League of Nations to see the Government associating themselves with other nations in such a humane Bill, and although on the surface the provisions made for the international aspect did not appear very drastic, still he hoped they would be more effective than they appeared to be. The drug habit was a matter which was well worth the attention of the Government, and he was glad they were beginning to take notice of this great evil in the social structure of our country. It was a growing evil and seemed to grow *pari passu* with certain types of civilisation. There was not much of it in our country districts; as a rule these habits were learned, developed, and practised in towns, and especially the bigger ones. The Government had selected, perhaps, the principal drugs that were used—opium and its derivatives, morphia and cocaine. The manner in which the Government proposed to attack the drug habit was quite on the right lines, and with one or two slight modifications he saw no reason why they should not have their Bill. He did not know what the references to medical men and dispensers exactly meant. Very often the excuse given by people who were victims of the drug habit was that the doctor prescribed it for them for certain ailments, and, unfortunately, after the immediate need for it had passed the patient, finding the effects of it pleasant, continued it until he became a victim and could not get rid of it. He presumed what was meant by one of the clauses giving power to the Home Secretary for "regulating the issue by medical practitioners of prescriptions containing any such drug and the dispensing of any such drugs," was that a chemist who dispensed a prescription containing any of these drugs would not be allowed to dispense it without a renewed prescription being given by the doctor. He did not know how many times a doctor might allow it to be dispensed without the renewed authority, but there should be some limit to that practice, otherwise they might go on taking the drug for a long time. He had often heard people who were addicted even to drink say that their doctor advised them to take some, as St. Paul said, for the stomach's sake, or for some other medical purpose. That was unfair to the doctors. There was one thing on which he would be inclined to blame some of his medical brethren in connexion with the drug habit, and that was the habit of taking medicated wines among women. He wished the Home Secretary had taken power to abolish medicated wine. If a doctor wanted to prescribe wine let him prescribe good honest port, or something of that kind, without it being mixed up with drugs. There was nothing that produced more drinking among women than medicated wines. With regard to the question of keeping books of all the drugs that were sent out, he hoped that any regulation that was adopted in regard to dispensing or prescribing, or in regard to the necessary book work in connexion with drugs would be framed in consultation with the representatives of the medical profession and of the pharmaceutical profession. Otherwise they might be drawn by somebody who might produce harm without giving the results required. For an offence against this Act a fine of £200 could be imposed, and he would draw attention on this point to the question of alcoholic poisoning. There were many thousands of deaths from that cause every year. The question of penalty ought to be very carefully considered before the penalties were finally adopted.

Mr. **WOOLCOCK**, who said he was the only person in that House who held a pharmaceutical certificate, and had acted for some years as secretary of the Pharmaceutical Society, welcomed from his experience the principal object of the Bill. He called attention particularly to Clause 7 of the Bill, paragraph B, which prohibited "the manufacture, sale, or distribution of any such drugs, except by persons licensed or otherwise authorised under the regulations." The effect of that might be that a Government Department would be able to supersede by regulations the important provisions of the Poisons and Pharmacy Act. He suggested that the Government might give them an assurance in regard to two or three important matters when the time came. The regulations to be made in under this Bill should be in addition to, and not in substitution of, the provisions of the Pharmacy Act and the Poisons and Pharmacy Act. He asked also for a promise on the Committee stage that a pharmacist who carried on business as a chemist should have the right to dispense and retail substances provided for under this Bill. The Government ought to assure the House that anyone who was charged with an offence under the Bill should have an appeal to some court.

Impracticable Regulations Obviated.

Captain **ELLIOT** said that they were very grateful to the Home Office for Clause 11, which provided that Regulations should be laid before Parliament which would have the power of considering them and of annulling them if necessary. That would help to avoid any fear that some committee of officials uld draw up impracticable regulations It was interest g to think that this Bill was being brought in primarily r an evil spreading, he thought, more from the United ates than from any other country That country was the eat temperance country at the moment It was a strange d noteworthy thing that alcoholism was in many ways mply the expression of a nervous weakness in the patient they tried to stamp out alcoholism by pure prohibition easures they drove the weak man from one form of drug another form of drug The fact that such a Bill as this as necessary was a very striking commentary on the trend some of our legislation Other countries that had managed get rid of alcoholism had found that some other vice d taken its place It tended to show that they should nl twice and thrice before interfering with the long tablished habits of the human race, especially of the estern races which had been accustomed to use alcohol moderation The American people had gone in for ohibition and had developed the drug habit to an extent together unknown in this country It might be simply coincidence, but the death rate from delirium tremens had ne up some 300 per cent In many cases the nervous athesis resulted in a trend either towards alcohol or some her drug, and if alcohol was prohibited then the other ug which was much more fatal, was resorted to in its ace He thought all medical men in the House and in the untry would like to draw the attention of the Government the necessity for dealing with patent medicines He gged the Home Office to confer with the Ministry of ealth and to disinter the valuable Report of a Committee that House which sat before the war on the subject of atent medicines, and to introduce legislation along the lines commended Various great evils had occurred from eople using these drugs under conditions which no medical an or chemist would dare to prescribe As to the Bill efore the House, they hoped that it was only the beginning international work for dealing with health problems as a hole The microbe knew no frontier, and disease was not mited to any kind of national flag

The Bill was read a second time

Coroners' Verdicts in Ireland

Colonel Sir ALEXANDER SPROT asked the Chief Secretary o the Lord Lieutenant of Ireland whether his attention had een directed to the evidence given on May 27th before the oroner s jury which inquired into the death of James Dalton at Limerick on May 15th last, whether Joseph Dalton a brother of the deceased, gave evidence that he was resent at a Dail Eireann inquiry into allegations against James Dalton of having relations with the police, and produced a document which was called Dail Eireann official verdict in the case of James Dalton whether the coroner accepted this document and handed it to the jury for their consideration, and whether it was proposed that the verdicts of illegal courts should be accepted by officials of the Government sitting in a judicial capacity and treated as material evidence for the consideration of the jury —Mr HENRY (Attorney General for Ireland) replied The answer to the first part of the question is in the affirmative It appears that a brother of the deceased man produced a document to the effect mentioned in the question, which was read The coroner is not an official of the Government, and the document in question was at once seized by the district inspector —Sir J BUTCHER Is there no control by the Government over the proceedings of coroners' courts?—Mr HENRY The coroner sits in a judicial capacity and is entitled to decide what documents he will receive or refuse to receive in evidence —Captain WEDGWOOD BENN Does the Government assume any responsibility in connexion with the verdicts brought in by coroners' courts?—Mr HENRY That depends entirely upon the verdict

Women, Young Persons, and Children (Employment) Bill

Major BAIRD moved the second reading of the Women, Young Persons and Children (Employment) Bill, the object of which, he explained, was to enact the necessary legislation to enable effect to be given to the Conventions which were agreed to at the recent International Labour Conference at Washington Clause 2 was not part of the Convention It asked the House to sanction the continuance of conditions which had been adopted during the war, under which women had been employed who could not have been employed under the Factory Acts Under those Acts the day ended at 8, the two-shift system had the two fold result of finding employment for something like 25 000 women and rather over 5000 young persons, with the accompanying increase in production and of work in the dependent industries —Lieutenant Colonel FREMANTLE entered a protest against Clause 2 from the point of view of public health If they were going to permit the employment of women in the factories up to 10 in the evening that would be a constant trouble in trying to get back any kind of home life, which was at the bottom of healthy homes They wanted to go against any legislation that tended further to break up family life It was totally unnatural for women to be employed night and day in the factories —Major BAIRD suggested that the House might give a second reading to the Bill and if the Government was unable to remove by its arguments the strong opposition to Clause 2 it was clear that that clause could not stand —The Bill was read a second time

FRIDAY, JUNE 11TH

Veterinary Surgeons Act Amendment Bill

The Veterinary Surgeons Act (1881) Amendment Bill was read a third time

The Health Resorts and Watering Places Bill

The Health Resorts and Watering Places Bill was read a third time

MONDAY, JUNE 14TH

Insanitary Areas

Mr MYERS asked the Minister of Health if he would state the number of separate areas upon which representations had been made by medical officers of health declaring such areas insanitary areas under the provisions of the Housing, Town Planning, &c, Act 1909 which were in the hands of the Local Government Board in August, 1914, and upon which no action had then been taken by the local authorities concerned, the number of houses and the population involved in these representations and the extent to which improvement schemes under the provisions of the Act had since been carried out, and in how many cases these insanitary areas still remained and the extent to which the houses affected were still occupied —Dr ADDISON replied There were three such areas comprising 890 houses, occupied by 4387 persons A local inquiry was held in each of these cases In two cases the local authorities were called upon to make improvement schemes, but proceedings had to be deferred owing to the war A scheme in regard to one of the areas has now been submitted to me, and a scheme in regard to another of them has been promised The third case was one of a small area (comprising 47 occupied houses) for the greater part of which an improvement scheme had already been made and confirmed The local authority were called upon to proceed to deal with the area, but action was interrupted by the war I have asked for a report on the present position of the area

Closing Orders

Mr MYERS asked the Minister of Health if he would state the number of dwelling houses which were still occupied in respect of which closing orders, numbering 22 115, were made in 1913 and 1914 upon the representations of the medical officers of health in England and Wales, and if he would state whether, under the Increase of Rent and Mortgage Interests (Restrictions) Bill now before the House it would be necessary for the tenants of these dwellings to secure an order from the county court judge to ensure them protection against the increased rent charges embodied in the Bill before the House —Dr ADDISON replied I regret that I am unable to give the information asked for in the first part of the question As regards the second part of the question under the proposals of the Bill the increases under paragraphs (*c*) (*d*) of Clause 2 (1) will not be chargeable if on production of a certificate of the sanitary authority or otherwise the court is satisfied that they should be suspended

General Medical Council Bill

The Direct Representatives of the General Medical Council Bill was read a second time

TUESDAY, JUNE 15TH

Unsuitable Artificial Limbs

Captain LOSEBY asked the Minister of Pensions if he was aware that ex soldiers who lost limbs during the recent war had in certain cases been supplied with unsuitable artificial limbs of an inferior quality, if he would state the policy of the Ministry in the matter, and if he would consider the advisability of issuing instructions that all artificial limbs supplied must be of the best quality procurable —Major TRYON (Parliamentary Secretary to the Ministry of Pensions) replied Every precaution is taken to see that only artificial limbs of the best quality are supplied Every limb must be passed by the surgeon of the hospital, and periodical inspection is given by officers of the Ministry In the event of any defect being subsequently found, readmission to a limb fitting hospital is arranged on application being made through the appropriate Local War Pensions Committee, in order that the defect may be put right or a more suitable type of limb supplied

Distribution of Artificial Limbs

Major COHEN asked the Minister of Pensions if he would state how many soldiers who were suffering from the amputation of a leg had been provided with their second artificial limb, and how many such soldiers were still waiting for the said limb —Major TRYON replied A duplicate artificial leg has been supplied in 6362 cases The number still to be supplied is 20,350

The Services.

ROYAL ARMY MEDICAL CORPS.

Major H. G. Pinches relinquishes the temporary rank of Lieutenant-Colonel.

Capt. A. M. Pollard to be temporary Major whilst specially employed.

Capt. N. T. Whitehead is seconded for service with the Egyptian Army.

D. E. Carter, late temporary Honorary Captain, to be temporary Honorary Captain.

Officers relinquishing their commissions:—Temporary Majors retaining the rank of Major: H. W. A. Burke, J. Jenkins. Temporary Captains granted the rank of Major: E. Kidd, (Acting Major) J. McF. Donnan, J. Bamforth, P. P. J. Stewart. Temporary Captains retaining the rank of Captain: E. Reavley, A. H. Greg, J. Humphreys, G. G. Bruce, M. J. Houghton, L. H. Werden, B. N. Sinclair, P. R. Browning, G. W. Spencer, B. P. Allinson, E. S. Hall, E. C. Dutton, D. Fettes, O. Heath, J. D. G. Stewart, F. G. Smyth, T. L. Harrison, M. E. Willcock, A. H. Hall, J. Paterson, L. W. Howlett, C. R. B. Von Braun, J. G. Elder, G. J. Fraser, G. E. A. Petrie, H. V. Walsh. Temp. Lieut. E. J. Hynes (retains the rank of Lieutenant).

SPECIAL RESERVE OF OFFICERS.

Capt. T. P. Chapman relinquishes his commission and retains the rank of Captain.

Lieut. (temp. Capt.) N. R. Hathaway resigns his commission and is granted the rank of Captain.

TERRITORIAL FORCE.

Capt. G. L. Thornton to be Lieutenant-Colonel and to command 1st Wessex Field Ambulance.

Majors H. Waite and H. Halton resign their commissions and retain the rank of Major.

Capts. W. P. Ferguson and A. L. Sharpin resign their commissions and are granted the rank of Major.

Capts. R. C. S. Smith, R. J. Chapman, T. Allen, and L. Colebrook resign their commissions and retain the rank of Captain.

London University Contingent, Medical Unit: Capt. W. Wright relinquishes his commission and is granted the rank of Captain.

TERRITORIAL FORCE RESERVE.

Capt. C. C. Grummitt, from the General List, to be Captain.

ROYAL AIR FORCE.

Medical Branch.—Capts. J. S. Prendergast, F. H. Bowen, A. L. Robinson, S. H. DeG. Pritchard are transferred to the unemployed list.

Lieut. C. H. Vernon relinquishes his commission.

Dental Branch.—Capt. G. F. H. Bloom is transferred to the unemployed list.

DEATHS IN THE SERVICES.

Surg.-Gen. James Cleghorn, I.M.S. (retired), C.S.I., Honorary Surgeon to the King, at his residence, Weysprings, Haslemere, Surrey, on June 14th, aged 79. He entered the Indian Medical Service in 1865 and served with the Bhootan Expedition (medal and two clasps). In 1891 he was appointed Inspector-General of Civil Hospitals in the Punjab and four years later became Director-General and Sanitary Commissioner. He represented the Government of India at the Venice Plague Conference in 1897. On retirement he was appointed Honorary Surgeon to the Queen in 1898.

Lieut.-Col. John Lancaster, I.M.S. (retired), on June 9th, at a nursing home, Streatham, aged 71. He was for many years Chief District Medical Officer of Vellore, N. Arcot, President of the Board of Examiners of Madras Medical College, and Civil Surgeon to the Governor and Staff at Coonoor. After 35 years of service he retired owing to ill-health caused by devotion to duty in connexion with the plague and cholera camps. For his work he twice received the thanks of the Government.

BROUGHT TO NOTICE.

The names of the following medical officers are to be added to those already brought to notice for services rendered in the spheres of operations detailed. All are members of the R.A.M.C. except where otherwise stated:—

France.—Temp. Lt.-Col. C. S. Myers, C.B.E.; Capt. C. S. O'Neill, O.B.E.; Capt. R. W. A. Salmon, O.B.E.

East Africa.—Temp. Capt. W. G. Cobb, D.S.O.; Capt. H. L. Duke, O.B.E., Uganda Med. Serv.; Maj. (temp. Lt.-Col.) W. V. Field, O.B.E., S. Afr. M.C.; Capt. (acting Maj.) S. J. V. Furlong, O.B.E.; Temp. Lt.-Col. J. Grinsell, O.B.E., S. Afr. M.C.; Capt. (acting Lt.-Col.) J. D. Kidd, O.B.E., M.C.; Lt.-Col. R. Milner-Smyth, O.B.E., S. Afr. M.C.

India.—Capt. (temp. Maj.) A. F. Babonau, O.B.E., I.M.S.; Maj. and Bt. Lt.-Col. (temp. Col.) F. A. F. Barnado, C.I.E., C.B.E., I.M.S.; Temp. Capt. J. Cairns, O.B.E.; Capt. (temp. Maj.) F. R. Coppinger, O.B.E.; Temp. Capt. S. K. Engineer, O.B.E., I.M.S.; Maj. (temp. Lt.-Col.) J. K. S. Fleming, O.B.E., I.M.S.; Maj. G. D. Franklin, O.B.E., I.M.S.; Maj. A. T. Frost, O.B.E.; Capt. W. A. Frost, O.B.E.; Capt. T. B. Heaton, O.B.E.; Maj. D. P. Johnstone, O.B.E.; Maj. T. W. Minty, O.B.E., I.M.S.; Lt.-Col. P. St. C. More, O.B.E., I.M.S.; Maj. R. B. Nicholson, O.B.E., M.C., I.M.S.; Maj. H. W. Pierpoint, O.B.E., I.M.S.; Lt.-Col. J. J. W. Prescott, D.S.O., O.B.E.; Capt. C. H. Smith, O.B.E., I.M.S.; Capt. (temp. Maj.) J. R. D. Webb, O.B.E., I.M.S.; Temp. Lt.-Col. Raghabendra Row, O.B.E., I.M.S.

North Russia.—Capt. (acting Maj.) W. N. W. Kennedy, O.B.E.; Lt.-Col. T. McDermott, O.B.E.; Capt. J. Renwick, O.B.E.

Salonika.—Temp. Capt. (acting Maj.) F. R. Brown, O.B.E.; Capt. (acting Maj.) B. L. Davis, O.B.E.; Dr. (Miss) E. B. Hollway, O.B.E.; Dr. (Mrs.) A. M. Livingstone-Learmonth, C.B.E., attd. R.A.M.C.

Siberia.—Maj. F. J. Collings, O.B.E., Can. A.M.C.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

HOUGHTON, M. J., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Referee under the Workmen's Compensation Act for County Court Circuit No. 43.

WYLIE, D. S., C.M.G., C.B.E., F.R.C.S., Inspector of Hospitals, Department of Public Health and Hospitals, New Zealand.

Great Northern Central Hospital: GORDON, E., M.B. Aberd., House Surgeon; and FINIGAN, F. O'C., L.D.S., Assistant to Dental Surgeon.

Certifying Surgeons under the Factory and Workshop Acts: REEVES, T. C., M.R.C.S. Eng., L.R.C.P. Lond. (Bollington); SMYTH, A. F., M.B., B.Ch. N.U.I. (Ballyhaunis).

Vacancies.

For further information refer to the advertisement columns.

Aylesbury, Royal Buckinghamshire Hospital.—H.S. £200.

Barnet, Wellhouse Hospital.—Res. Asst. Med. Supt. £250.

Barrow-in-Furness County Borough.—Asst. M.O.H. and Clin. Tuberc. Officer. £500.

Battersea General Hospital (Incorporated), Battersea Park, S.W.—Res. M.O. £200.

Belgrave Hospital for Children, Clapham-road, S.W.—H.S. £100.

Bermondsey Medical Mission.—Female Locum Tenens. £200.

Birmingham General Hospital.—H.S.'s and H.P. Also Res. An- £100.

Bolton Infirmary and Dispensary.—Female Second H.S. £250.

Bradford Children's Hospital.—H.S. £200.

Bradford City.—Asst. Bacteriologist. £600.

Brighton, Hove and Preston Dispensary.—Res. M.O. £200.

Brighton, Royal Sussex County Hospital.—Jun. H.S. £130.

Bristol General Hospital.—Cas. H.S. £175.

Burnley, Victoria Hospital.—H.S. £250.

Bury County Borough.—Venereal Diseases Officer. 3 gs. a session.

Canning Town Women's Settlement Hospital, Balaam-street, Plaistow, E.—Female Hon. Asst. P. Also Female Res. M.O. £150.

Cardiff, King Edward VII. Hospital.—H.S. £200.

Cardiff, King Edward VII. Welsh National Memorial Association.—Asst. Tuberc. P.'s. £500.

Central London Throat and Ear Hospital, Gray's Inn-road.—Th Asst. S.

Chelsea Infirmary, S.W.—Second Asst. M.O. £325.

Chichester, Royal West Sussex Hospital.—H.S. £200.

City of London Maternity Hospital, City-road, E.C.—Res. M.O. £1

Colchester, Essex County Hospital.—H.P. £200.

Coventry Education Committee.—School Dentists. £400.

Croydon County Borough.—Asst. M.O.H. and Asst. Sch. M.O. £50 Also Female Asst. M.O.H. for Maternity and Child Welfar Work. £500.

Doncaster Royal Infirmary and Dispensary.—Asst. H.S. £225.

Donnybrook, Dublin, Royal Hospital for Incurables.—Res. M.O. £200.

East Suffolk County Education Committee.—Dental Surgeon. £500. Asst. School M.O.'s. £500.

Elizabeth Garrett Anderson Hospital, Euston-road.—Female Sen. Asst. M.O. £200.

Federated Malay States.—Radiologist. £840-980.

Frimley, Brompton Hospital Sanatorium.—Asst. Res. M.O. £250.

General Lying-in Hospital, York-road, Lambeth, S.E.—Registrar.

Glasgow University.—Lectureship in Ophthalmology.

Gloucester County Asylum.—Jun. Asst. M.O. £300.

Gloucestershire Royal Infirmary and Eye Institution.—H.P. £175.

Gravesend Hospital.—H.S. £200.

Great Northern Central Hospital, Holloway, N.—Cas. O. £200.

Halifax Royal Infirmary.—Senior, Second, and Third H.S.'s. £350, £300, and £275 respectively.

Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—Asst. Res. M.O. £150. Also H.P. 30 gs.

Hospital for Sick Children, Great Ormond-street, W.C.—Cas. M.O. £200. Also Med. Reg. and Path. £200.

Huddersfield Royal Infirmary.—Sen. H.S. £250.

Hull Royal Infirmary.—Asst. H.S. £150.

Huntingdonshire County Council.—Female Asst. County M.O and Asst. Sch. M.O. £500.

Italian Hospital.—H.S. £150.

Lancaster Royal Infirmary.—H.S.

Leamington Spa, Warneford, Leamington, and South Warwickshire General Hospital.—Res. H.P. £200.

Leeds City.—Female Asst. M.O. for Maternity and Child Welfare. £500.

Leeds City Tuberculosis Sanatorium.—Res. Asst. M.O. £300.

Leeds Public Dispensary.—Res. M.O. £200.

Leicester, City Mental Hospital, Humberstone.—Asst. M.O. £600.

Liverpool Stanley Hospital.—Res. P. and S. £150.

London County Council Hospital Service.—Sixth and Seventh Asst M.O.'s. £300.

London Fever Hospital, Liverpool-road, Islington, N.—Res. Med. Supt. £400. Also Asst. Res. M.O. £200.

London Temperance Hospital, Hampstead-road, N.W.—Res. M.O. £200.

Manchester, Ancoats Hospital.—H.P. £150. Also Two Jun. H.S.'s. £100.

Manchester Royal Infirmary, Roby-street.—Second Res. M.O. £100. Also H.S.'s. £50 first six months, £100 second.

Margaret Street Hospital for Consumption, 26, Margaret street, W—Asst Hon P

Middlesbrough Education Committee—Sch Dent £400

Middleton in Wharfedale Sanatorium, near Ilkley—Asst M O £500

Miller General Hospital for South East London Greenwich, S E—Res Cas O £150 Also H S £100 Also Orthopædic S and Hon P

Ministry of Pensions Special Surgical Hospital, Shepherd s Bush, W—Senior Part-time S

National Dental Hospital, Great Portland street, W—Med Supt £250

Newcastle-upon Tyne Education Committee—Asst Sch M O £500 Also Dental S £400

Newcastle-upon Tyne Hospital for Sick Children—Sen and Jun Res M O 's £250 and £200 respectively

Northampton General Hospital—H S £200

Nottingham City Asylum—Second Asst M O £400

Prison Medical Service—M O s £300

Reading Royal Berkshire Hospital—H S £200

Rochdale Infirmary and Dispensary—Sen H S £250

Wolverhampton and Staffordshire General Hospital—H S £200

Worcester County and City Mental Hospital, Powick—Jun Asst M O £300

Worcestershire County Council—Asst County M O s and Sch Oculist £500 each

Wormley Infant Welfare Centre—M O 30*s* per session

The Chief Inspector of Factories, Home Office, S W, gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Buckhaven, Dulais Valley, and Forkhill

Births, Marriages, and Deaths.

BIRTHS.

CLIVE MATTHEWS.—On June 14th at St Leonards on Sea the wife of L Clive Matthews, L D S R C S E of a son

DAWSON.—On June 4th, at Bury St Edmunds, the wife of Geoffrey Dawson L D S, R C S Eng of a son

WACHER.—On June 13th at St George s place, Canterbury, the wife of H Stewart Wacher, M R C S, L R C P, of a daughter

WALKER.—On June 10th at Spencer House, Tetbury, Gloucestershire, the wife of T Warburton Walker M D, of a daughter

MARRIAGES.

FINNY—BUNFORD SAMUEL.—On June 8th, by licence at All Saints Church, Kingston upon Thames William Evelyn St Lawrence Finny, M D, J.P, Barrister at Law, to Emily Grace Bunford Samuel, elder daughter of the late Isaac Bunford Samuel, and Mrs Cooper Turner, of Marlow House Kingston upon Thames

MILLER—DIMOND.—On June 1st, at Kilglass Parish Church, by the Rev W A Scanlen, cousin of the bride, Henry C D Miller, M B late Captain, R A M C (T C), of Whittington Moor, Chesterfield, to Wilhelmina Esther Dimond, late Q A I M N S (R), second daughter of Francis Dimond, J P, Tully House, Lenamore Rathowen, Ireland

DEATHS.

CLEGHORN.—On June 14th, at his residence, Weysprings, Haslemere, Surrey, Surgeon General Cleghorn, C S I, K H S aged 79

KERR.—On June 8th, at South Lodge, Dorchester, Elias William Kerr M D M Ch, B A, aged 70

LANCASTER.—On June 9th, at a nursing home in Streatham, Lieutenant Colonel John Lancaster, I M S, retired

SEWILL.—On June 11th, at Sand Dene Meadvale, Redhill, Henry Sewill M R C S, aged 77

N.B.—A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages, and Deaths

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Thursday and Friday, June 24th and 25th.

LARYNGOLOGY (Hon Secretaries—Irwin Moore, Charles W. Hope)

SECOND ANNUAL SUMMER CONGRESS

Exhibition of Pathological Specimens and Drawings, Surgical Instruments, and Drugs

Thursday —2 30 to 5 30 P M, *Reading of Papers on Cancer of the Throat, followed by Discussions*

7 30 P M, Dinner at the Cafe Royal

Friday —10 A M to 1 P M, Reading of Papers and Discussions left over from the previous day

2 30 to 4 P M, Demonstrations

4 P M, Clinical Meeting

RESEARCH DEFENCE SOCIETY, at the House of the Medical Society of London, 11, Chandos street Cavendish square, W.

WEDNESDAY, June 23rd —3 45 P M, Annual General Meeting Address —Col McCarrison, I M S Vitamines in their Relation to Health Exhibition of Specimens

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, at the Kensington Town Hall

FRIDAY, June 25th —7 45 P M, Reception 8 15 P M, Cavendish Lecture —Prof C S Sherrington Posture Followed by Annual Conversazione

TUBERCULOSIS SOCIETY, at Cardiff

SATURDAY, June 26th —Papers will be read by Dr Brownlee, Dr de C Woodcock, and Dr H Ellis

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East

TUESDAY, June 22nd—5 P M, Croonian Lectures —Dr A F Hurst The Psychology of the Special Senses and their Hysterical Disorders (Lecture IV)

LONDON HOSPITAL MEDICAL COLLEGE (SURGICAL UNIT) in the Units Lecture Theatre, London Hospital, E

Special Course of Lectures open to both Students and Post Graduates

Three Lectures on The Acute Abdomen—

WEDNESDAY, June 23rd, AND FRIDAY —4 P M, Mr R Howard (Lectures I and II)

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S W

MONDAY, June 21st —2 P M, Dr Melville X Ray Department

TUESDAY —2 P M, Sir J *Dundas Grant Throat Department* 2 30 P M, Demonstration —Dr Burrell Vital Capacity

WEDNESDAY —10 30 A M, Dr Punch Demonstration of Museum Specimens 2 P M, Dr Gosse Cardiographic Department 2 30 P M, Demonstration —Dr Punch Tuberculin, and *other Tests for Tuberculosis*

THURSDAY —10 30 A.M, Dr Burrell Artificial Pneumothorax 2 30 P M, Demonstration —Dr Fenton Conduct of Tuberculosis Dispensary

FRIDAY —2 P M, Dr Melville *X Ray Department* 2 30 P M, *Demonstration —Dr Burrell Conduct of Tuberculosis* Dispensary

SATURDAY —1 P M, Dr Batty Shaw Special Demonstration in the Out-patient Department

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen square, W C 1

MEDICAL SCHOOL

MONDAY, June 21st —2-3 30 P M, Out-patient Clinic Dr Collier 3 30 P M, Dr Kinnier Wilson Paralysis Agitans

TUESDAY, June 22nd —2-3 30 P M, Out patient Clinic Dr Grainger Stewart 3 30 P M, *Dr Risien Russell Disseminated* Sclerosis

WEDNESDAY, June 23rd —2 P M, Dr Grainger Stewart Epilepsy 3 15 P M, Demonstration of Fraenkel s Exercises I

THURSDAY, June 24th —2-3 30 P M, Out-patient Clinic Dr *Farquhar Buzzard* 3 30 P M, *Dr Saunders Myelitis*

FRIDAY, June 25th —2-3 30 P M, Out-patient Clinic Dr Gordon Holmes 3 15 P M, Demonstration of Fraenkel s Exercises II

Fee for Post-Graduate Course £7 7*s* C M HINDS HOWELL, Dean

NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland street, W

MONDAY, June 21st —5 30 P M, Post-Graduate Lecture —Dr Price Auricular Fibrillation

KING S COLLEGE HOSPITAL MEDICAL SCHOOL (UNIVERSITY OF LONDON)

A Course of Post Graduate Lectures on Syphilis is being given by various members of the staff of King s College Hospital during the present year

FRIDAY, June 25th —9 15 P M, Prof A Whitfield Treatment of Syphilis I

NORTH EAST LONDON POST GRADUATE COLLEGE, Prince of Wales s General Hospital, Tottenham, N

MONDAY, June 21st —2 30 P M, *Mr J B Banister Gynæcological*

TUESDAY —9 45 A.M, Lieut.-Col R H Elliot Selected Eye Cases and Operations 2 15 P M, Selected Cases —Dr R M Leslie Diseases of the Lung 3 15 P M, Clinical Lecture —Mr Benians Chronic Infections of Mucous Surfaces 4.30 P M, Lecture —*Lieut -Col Byam, O B E The Debilitated Man from the Tropics*

WEDNESDAY —2 30 P M, Dr W J Oliver Dermatological

THURSDAY —2.30 P M, Mr N Fleming Ophthalmological Dr J Metcalfe Radiology

FRIDAY.—2.30 P.M., Dr. C. E. Sundell: Diseases of Children.
SATURDAY.—3 P.M., Mr. H. W. Carson: Selected Surgical Cases.
Daily:—2.30 P.M., Operations, Medical and Surgical Clinics, &c.

ST. MARYLEBONE GENERAL DISPENSARY, 77, Welbeck-street, Cavendish-square, W.
Post-Graduate Course on *Infant and Child Welfare.*
TUESDAY, June 22nd.—10.30 A.M., Dr. E. Pritchard: Practical Demonstrations on the Management and Feeding of Infants and Young Children—Lecture VII., The Uses of Dried *Milk and Patent Foods.*
THURSDAY.—3 P.M., Lecture VIII., The Management of Difficult Cases.

INFANTS HOSPITAL, Vincent-square, Westminster, S.W.
TUESDAY, June 22nd.—5 P.M., Dr. R. Vincent: Practical Points in Infant Feeding.

UNIVERSITY OF LONDON.
Advanced Lectures in Physiology to Students of the University and others interested in the subject.
A Course of Eight Lectures on the Bio-Chemistry of Sterols will be given in the Physiological Laboratory of the University, South Kensington, S.W.
TUESDAY, June 22nd.—5 P.M., Lecture VI., Mr. J. A. Gardner.

UNIVERSITY OF SHEFFIELD—FACULTY OF MEDICINE POST-GRADUATE LECTURES, at the Sheffield Royal Infirmary.
WEDNESDAY, June 23rd.—4 P.M., Prof. Connell: Lesions of Foot and Pott's Fracture.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE CLINIC.
TUESDAY, June 22nd.—4.30 P.M., Lecture:—Dr. E. M. Brockbank: Anæmias and their Diagnosis.

MANCHESTER FRENCH HOSPITAL POST-GRADUATE LECTURES, 24, Acomb-street (behind Whitworth Park).
THURSDAY, June 24th.—4.30 P.M., Dr. A. C. Magian: Chronic Tubo-Ovarian Inflammation and its Relation to Venereal Disease. Operative Treatment.

Communications relating to the editorial business should be addressed exclusively to the Editor of THE LANCET, 423, Strand, London, W.C. 2.

Dr. Vere G. Webb points out that Miss Millicent Vere Webb, the lady superintendent of the Dufferin Victoria Hospital, is also senior surgeon to the institution, and was recommended for the Kaisar-i-Hind medal principally for her surgical work.

Notes, Short Comments, and Answers to Correspondents.

THE HYGIENE OF THE FEET AND PHYSICAL EFFICIENCY.

BY FREDK. JOHNSON, M.B. LOND., F.R.C.S. ENG.

NOW that renewed attention is being bestowed on all matters that affect the physical fitness of the youth of the nation, it may not be amiss to call attention to the relation that subsists between sound feet and health. Modern civilisation requires the encasing of the foot in a leather covering. The foot has thus been rendered a delicate member, to a degree only to be appreciated after a study of the human foot among a primitive people who live and grow up unshod, or at the most use a light sandal.

Contrasts.

Let us take, then, for comparison two types of the human foot: (1) the foot of a desert-dwelling Arab; (2) the foot of an artisan of one of our large towns. A study even of the skeletal parts will reveal differences in the degree of development of individual bones, but it is in the living feet that the contrast is most marked. It has been my lot to spend nearly 20 years amongst the Arabs of Eastern Palestine and Mesopotamia. It has also fallen to my lot to see something of our recruits under training during the early years of the war.

It would be interesting to know the statistical returns of recruits who came under treatment for defects of the feet—such as hammer-toes, overlapping toes, flat-foot, ingrowing toe-nail, various forms of tender feet—and to estimate the loss of time which the cure of these defects entailed.[1] I may remark in passing that the Army and Navy pattern of boot seemed, in my judgment, all that could be desired. If, in addition, the statistics were to include those suffering from various degrees of trench foot, the measure of the evil will be still more apparent. It cannot be doubted that the tenderness of the foot of civilised man and its enfeebled vaso-motor mechanism, unable to adapt itself to low temperatures, predisposes that member to the various pathological conditions comprised in the term trench-foot. A department of the Ministry of Health might with advantage pursue this inquiry and gather these statistics from the R.A.M.C. war records.

In considering the causes that have operated in producing the feeble, pallid, and delicate appearance of the foot of the average civilised man, it should be noted that whilst a mechanical cause—compression—accounts for a good deal, the exclusion of light and air have not been without influence. In the case of the bare-footed Arab type it is easy to understand the effect of the actual contact of the sole of the foot with the earth—the friction on the skin, the pressure upon the numerous small joints of the foot of the body weight, with distribution unimpeded by compressing footwear, and, lastly, the complete freedom of the circulation, both cutaneous and deep, the wholesome influence of light and air, and the unimpeded activity of the numerous sweat glands. I would emphasise the observation that, marked as is the difference in outward configuration of the two types of foot, the difference in physiological, especially circulatory, efficiency is still more marked. I have seen the bare-footed Arab in cold mountainous parts and have wondered at his comparative insusceptibility to cold feet.

The High Heel and the Pointed Toe.

When the boot is ill-fitting or ill-shaped the effects of compression are inevitably exaggerated. These effects are more commonly seen in the case of women, for reasons easily explained by reference to the lines of the modern woman's shoe. It should not be forgotten that the penalty of delicate feet is not confined to those long-suffering members alone, but secondary effects of an untoward kind follow inevitably. I allude to the unwillingness to take sufficient exercise and the impairment of general health as the result.

What puzzling thoughts must come to a professor of anthropology as he surveys the boots and shoes exposed for sale in a modern boot shop, especially the footwear of women and children. How is it that he sees the shoe of the young child with a perfect anatomical shape, a low heel, and ents of toe space, and then as he turns to the footwear of der girls and women he finds such a steady alteration shape and style Apart from simple growth there has een no change in the anatomy of the foot Not until our naginary professor turns to the region of female psychogy does he get any explanation of the phenomenon He ill further discover that having reached an explanation he still far from instituting an acceptable remedy to an berration so pernicious in its results The remedy of the vil, however, is not in his department, and for this he may e thankful

---

[1] There are, of course, no statistics available for a corresponding number of women. If there were, the result would be still more eloquent, because the incidence of irregularities of the toes and feet is greater in women than men.

Many of our ideas of physical culture and æsthetics owe eir origin to the ancient Greeks, what these ancient oneers of grace and beauty would say to much of modern otwear and its accompaniment—faulty gait—I must leave to he imagination The prevalence of faulty gait is not suffi ently recognised in this busy age, however, it is wide pread and in its minor manifestations at least owes its rigin to the foot and its coverings

Another adverse influence to the well being of the foot is orthy of mention in passing—the hard unyielding surface f our roads and pavements—an evil much increased since he rise of motor traffic In making the above comparison etween the foot of modern civilised man and the foot of he present day Arab or ancient Greek, I am not unmindful f the important item of climate as a factor in the selection f suitable footwear No doubt my residence in the East nd my contact with Orientals have coloured my remarks have tried to emphasise the divergence between the two ypes of foot—that of the Arab and that of civilised man—nd this divergence is barely appreciated by those who have ot lived amongst a primitive people

Some Suggestions

I now pass to one or two suggestions which aim at raising the physiological tone of the feet Firstly, I would remark that, in a matter of this kind, counsels of perfection are of little use, and conventional ideas must, to some extent be respected The most that can be advised is a corrective designed to counteract the effects of unfavourable causes Something, too can be effected on educational lines

The first recommendation is the adoption in schools and camps—holiday camps for boys and girls, and military establishments—of a special bare foot drill, as an integral part of the usual physical culture training I know that the curriculum, both in our schools and in military camps, is already a full one But if the evil of "delicate feet" is as great as I have indicated, it will be no waste of time if an hour, three days a week, winter and summer, be devoted to this special form of physical culture The children of our elementary schools would not, I believe, require much persuading to follow the suggestion, objections, if they arise, would more likely come from the teachers As to the ground on which the drill should take place, I would suggest two types likely to be serviceable (1) an ordinary grass field, (2) a ground with a surface of fine cinder ash, well rolled, and firmly set This latter would cause friction and thereby promote the circulation of the skin of the sole I would further suggest that medical inspectors of schools should include amongst their duties the inspection of the feet and footwear of children, and that the official forms supplied by the county educational committees should provide for this The wearing of sandals without stockings should be encouraged, especially in young people, during the summer months

Lastly, educational propaganda should be instituted Colleges of physical culture are increasing both for men and women Consider for the moment those for women, for perhaps it is amongst women that education on the subject is more needed *Young women leave these colleges after three years'* study, well grounded in the essentials of anatomy and allied subjects which form the foundation of physical culture These qualified teachers should be looked to as a means of educating the uninitiated in schools, and demonstrating to their pupils the mechanics of the normal human foot, with its arches and multiple small joints, and the part the arches and joints play in the functions of bearing the body weight and of locomotion The mechanical effect of the high heel, combined with the pointed, stiff and unyielding toe cap, under the influence of the body-weight, should also be demonstrated Surely, with a ittle enlightenment of this kind, the penalties of wearing the "fashionable shoe" would not be so lightly ncurred as in the days of ignorance The demonstrator hould not omit to point out the effects upon a walker up and own hills of high heels and pointed toes Something would gained if the height of the heel could be reduced even to n inch

Physical culture is recognised as a subject of national importance, upon the feet rests the whole superstructure of man's erect form Might not some of the time now devoted to the culture of the superstructure be spared with advantage to the well being of the lowly, hidden feet?

PUBLIC HEALTH IN NIGERIA, 1918

A REPORT on the Blue book for the year 1918, drawn up by the Acting Governor, Mr A G Boyle, C M G, has just been presented to the Imperial Parliament A considerable increase in the number of resident Europeans is noted In the Northern Province it was estimated that there were 939 Europeans at the end of 1918, of whom about 495 were officials In the Colony and Southern Provinces there were 2000 Europeans, about 1250 being officials The native population of the Northern Provinces is estimated at 8 537,369 and of the Southern Provinces and Colony at 7,856,000, a total of about 16 millions The average density in the Northern Provinces would therefore be about 33 to the square mile, and in the Southern Provinces and Colony about 98

Influenza

On the whole the general health of the community in the Southern Provinces in 1918 compared unfavourably with previous years The great pandemic of influenza reached Nigeria towards the end of September raged during October, and declined rather abruptly in November Imported into Lagos by sea from the Gold Coast in spite of unremitting efforts on the part of the sanitary authorities it was but a matter of time till the disease had spread all over the country Calabar was the last to suffer owing to the infrequency of the shipping service between there and ports to windward and the epidemic was at its height there when it had practically died out in Lagos The epidemic did not present any features different from those observed in other parts of the world, unless it was in its severity Gastro-intestinal types were noted but in the great majority of the cases the brunt of the disease fell on the respiratory system All the deaths among the Europeans were due to septic broncho pneumonia It is difficult to estimate either the incidence of the disease or the mortality except in Lagos where there is a properly organised health department and where registration is compulsory In that centre a case incidence of 50 per cent, with a mortality of 5 per cent, would probably be a low estimate Among the poor and intensely ignorant both the incidence and mortality must have been very much higher It is estimated from the Register of Deaths and a comparison of the death rate during the epidemic with the same periods in previous years, that 1 5 per cent of the population of Lagos died of influenza

Other Diseases.

Amongst the native population the most prevalent diseases excluding influenza, were affections of the digestive and respiratory systems, infective diseases and rheumatic and skin affections Anæmia is responsible for a great deal of ill health and invaliding Gout among both Europeans and natives is fairly common There were only 9506 cases of malaria in 1918 as compared with 11 804 in 1917 Two cases of yellow fever occurred, one European and one native both were fatal One case of trypanosomiasis was treated at Ibadan and one at Lagos, the Ibadan case was imported from the Northern Provinces whilst the Lagos case was an old one which had been under treatment in England There were 29 cases of blackwater fever in Europeans with 4 deaths the native had this disease and recovered 2231 cases of chicken pox which is endemic and from time to time epidemic were recorded with 10 deaths—a high rate of mortality for this disease There were 439 cases of small pox, with 74 deaths or a case mortality of 168 0 per 1000 Nothing approaching a serious outbreak of the disease occurred The incidence of small pox is principally confined to the dry season Dysentery is for the most part of the amœbic variety Among Europeans the case incidence was practically the same as in the previous year 40 cases were recorded, but this gives a low estimate of the number who are carriers of the amœba Emetine and Alcresta ipecac have given good results in the treatment Amongst natives 920 cases were recorded with a mortality of 16 3 per cent, as against 1059 with a mortality of 11 2 per cent in 1917

A DEMONSTRATION OF ARTIFICIAL LIGHT LIMBS

WE drew attention in an annotation published in our issue of June 12th to the interesting medical sections of the exhibits (Army, Naval, and Air Forces) now on view at the Imperial War Museum at the Crystal Palace Amongst other things claiming special notice is the exhibit of light legs in the Army Medical and Red Cross Section of the Museum, shown under the auspices of that worthy institution, "The Disabled Society" The object of this society is to ensure that the best type of artificial limb shall be brought within the reach of all ranks It is pointed out that it was early evident that the heavy wooden limbs needing harness over the chest and shoulders made the task of the wounded man a heavy one, and it is now established that with a light clean limb simply attached with a pelvic band a man may regain practically all his previous activity, and not only earn his living in most occupations, but enjoy games and sport without undue fatigue Lieutenant General Edward Bethune expresses the hope that, pending the adoption by the authorities of a standard light limb, such appliances will be encouraged and find a place on the market Meantime the society announces that any information in their possession is freely at the service of anyone requiring such information, and the evidence of actual wearers of these limbs is available The activities of the Disabled Society are recorded from time to time in a publication known as "The Ex Service Man" The temporary address of the society is 123, Church street, Chelsea, S W 3 The organisation should arouse wide sympathy and substantial support.

WOMEN'S HOLIDAY FUND.

THE object of this fund, which began its work in 1895, is to help the London working woman to have a week or a fortnight's holiday by the sea or in the country. In spite of higher wages there are many who have to spend their weekly money on the bare necessities of life, and have no margin left for holidays. Help is needed specially for the woman dependent on her own exertions for her livelihood, and for the mothers of large families.

All applicants pay as much as they can towards their expenses, but the society has to meet about two-thirds of the total cost. Donations should be sent to the Secretary of the Women's Holiday Fund, 76, Denison House, 296, Vauxhall Bridge-road, S.W. 1.

EASTERN AND WESTERN MEDICINE.

AT the last meeting of the Madras Legislative Council heated discussion centred round a resolution which recommended the appointment of a committee for the investigation and encouragement of Ayurvedic and Unani systems of medicine now in vogue in the Presidency. In moving the resolution an Indian councillor said that the depreciation of the Ayurvedic system of medicine was quite unwarranted. The Ayurvedic system was just as scientific as the Western system of medicine. The medical aid provided by Government to taxpayers was totally inadequate. The speaker declared that, in his opinion, in cases of snake-bite and rabies the Western treatment failed, while the Eastern, to his knowledge, succeeded.

THE CHARACTERISTICS OF THE ULSTERMAN.

Sir John Byers has written an interesting and topical pamphlet with this title. The study of character and temperament is no less important to the doctor than it is to the statesman who at the present juncture may find help in the solution of difficult problems by a perusal of Sir John Byers's anecdotal study. As the author points out, in no part of the British empire have there been so many different races in various periods as in Ulster, while the province differs from the rest of Ireland in its physical aspects. Reticent and parsimonious in the use of words, unless he is sure of their effect, the Ulsterman, even in sickness, does not care to waste his breath. An instance is given of a hospital patient who never spoke for a fortnight save by *pointing and nodding*. When roused, however, the Ulsterman can speak with passion, quickness, and alertness, and is stern, dogged, and unyielding. His suspicion of compliments is indicated by the saying, "He's a dale too sweet to be wholesome." Industry, enterprise, and perseverance, with much "judition"—i.e., sound judgment—are also characteristics, in accordance with Sir John Byers's summary.

THE WELFARE OF THE PROFESSION AND THE COUNTRY.

To the Editor of THE LANCET.

SIR,—The recent resolution of the Insurance Commissioners to pay mileage *from the doctor's residence* rather than from the nearest doctor seems detrimental to both, since it may lead to an immense usage of transport material—motors, carriages, coachmen, chauffeurs, &c. All doctors are qualified and presumably equally able. The idea that an individual of the public may have that one doctor, however distant he may be, alone understands his case, is, except in very special instances, illusory; in fact, pure imagination. As to the immense amount, perhaps, to be used in extra transport, will it not be wasted? Would not the country be richer were such an amount saved? Can the country afford waste at the present time? The doctor during the long hours of the passive inactivity of transport in all weathers cannot expect to have a healthy time of it. I suppose it will mean shortening of his life, and his advice—well, I would rather have it from a healthily employed man. Legislative wisdom might perhaps travel on the lines of confining the people to the nearest doctor, like in rural districts the people often go the nearest place of worship, and treating them otherwise as having luxuries—taxable luxuries of mileage to pay. The doctors then might be fully employed, many more living in country parts than now, and mostly able to get through their work on their feet healthily.

I am, Sir, yours faithfully,

W. P. D.

June 4th, 1920.

"THE ROTTEN MEDICAL PROFESSION."

UNDER the above title we have received from a serious correspondent this letter for publication:—

> The country is quite glutted with persons holding medical qualifications, yet competent doctors were never more difficult to find. Only about 10 per cent. of doctors are trained up to the point of being able to perform operations or set broken bones.
>
> Third- and fourth-rate medical schools enrol students (for the sake of the fees) in numbers far in excess of the clinical material available for their training. These inefficients become club doctors, panel doctors, sixpenny doctors, and so forth. Much time and money is wasted before patients can find a doctor competent to deal with their case.
>
> Stringent "State" regulations should ensure that every medical student obtain the opportunity of an efficient training up to being able to perform operations, no favoured students being allowed in the hospitals after the other students have been dismissed.
>
> A single "State" qualification ought to replace the many useless diplomas at present in vogue, and the holder's possession of it should be unassailable and absolute. By virtue of being qualified alone, every medical person should automatically become a member of the staff of the hospital serving the district in which he or she is a permanent resident.
>
> No medical panel should be allowed to be sold, and a triennial dissolution of all panels should be enforced to give new beginners a chance. The system enabling rings of doctors to keep the appointments amongst them ought to be abolished, one medical man one medical appointment only.

The writer, we feel sure, believes every word of what he has written, having taken what he would term his facts from gossip. He does not know the need for doctors, but repeats the old story of a glut. He does not know of the standardising work of the General Medical Council in education. He seems not to know that there are difficulties in the institution of a one-portal system *which could only* be removed by legislation. We recommend our correspondent to read the Interim Report of the Consultative Council on Medical and Allied Sciences, and to see what is there *projected for giving the general* practitioner opportunities for the best scientific work.

Hunterian Lecture

ON

THE INFLUENCE OF NERVE IMPULSES ON VISCERAL DISORDERS.

Delivered at the Royal College of Surgeons of England on Feb. 9th, 1920,

By H. TYRRELL GRAY, M.A., M.C. Cantab., F.R C.S. Eng.,

SURGEON TO OUT PATIENTS, WEST LONDON HOSPITAL SURGEON TO HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, AND TO THE ITALIAN HOSPITAL, HUNTERIAN PROFESSOR (LATE ARRIS AND GALE LECTURER), ROYAL COLLEGE OF SURGEONS OF ENGLAND

(Concluded from p 1304)

COLOPEXY.

THIS study embraces a series of 123 cases, in which fixation, partial or "complete," was performed in 106 Since my experiments on shock I started out with the hypothesis that mesenteric inhibitory nerves could be stimulated by mechanical traction Experimental evidence supported such a view, and it is not surprising that visceral disorders should have been approached from this standpoint. The relief of such a strain by a normal anchorage of the bowel would clearly cure the symptoms, provided secondary lesions were not too firmly established Accordingly, I have during the last eight or nine years practised various operations for fixation of the cæcum, ascending and transverse colon, being originally led to do so after reading a report of Wilms's paper on *cæcum mobile* (published in 1904)

In order to facilitate a detailed analysis I have divided these cases primarily into two main groups according to the situation of the chief mesenteric strain · (A) tension on the ileo cæcal and ileo colic mesentery, (B) tension on the transverse mesocolon Thus, A arises in excessive mobility of the cæcum and ascending colon; and B when there is marked proptosis of the transverse colon A and B may exist together in general viceroptosis In all these fixation operations the object has been the transference of an excessive mesenteric strain to a region which is innocuous

A. *Cæcopexy and Ascending Colopexy*

From the first I have never performed Wilms's "pocket operation, but have always attempted to reproduce as accurately as possible the normal result of mesenteric fusion Depending on whether the cæcum alone or the cæcum and ascending colon is to be fixed, I *open the peritoneum of the posterior wall and iliac fossa about* ½in external to the line of the mesenteric attachment, from a point just short of the brim of the pelvis as far up as necessary (Fig 4 (A–B) and Fig 6 (X–X')) The suture of the internal cut edge of the peritoneum to the postero internal aspect of the cæcum is commenced at and includes the *meso-cæcum (in order to obviate the* possibility of internal hernia) The sutures are continued downwards, the apex of the cæcum being sutured to the lowest point of the peritoneal incision From this point upwards to the upper extremity of the peritoneal incision the cut edge is sutured to the external *tænia muscularis All sutures should include the muscular* wall of the bowel The cæcum and ascending colon are thus rendered extra peritoneal in their posterior aspect over the required area That such an attachment proves permanent I have twice had the opportunity of establishing, once in a case I operated *upon again a long time afterwards,* and *once at an* autopsy after accidental death from coal gas poisoning

Of 53 cases, no fixation was performed in 7, of which 3 were not operated upon at all, and the only one of these I can trace is relieved by corsets, but still suffers pain Of the remaining 4 cases, 3 have been traced, 2 are *cured,* and the *other has* had a recurrence of pain This leaves 46 cases on whom fixation of cæcum or cæcum and ascending colon was performed Of these I have not been able to satisfy myself, either by letter or personal interview, of the late results in 13, some of which were operated on a good many *years ago I have thus a series of* 33 cases in which the end results can be traced over a varying number of years and in 2 of these (though I have no news of them lately) the result was entirely satisfactory *for a* long time after the operation

The figures for this series —

Cured	78 7%	—i e 84% satisfactory
Improved	6 0%	
Failed	9 0%	—i e , 15% failures
Symptoms recurred (after some time)	6 0%	

With regard to the failures I have made careful investigation and will discuss them in a moment, but it is clear that little can be learnt from the percentage of successes alone The figures agree in the main with those given by Wilms (75 per cent cures), but the details are instructive and deserve some elaboration The groups of symptoms for which this operation has been performed are three

(1) *Recurrent acute attacks of pain* resembling acute appendicitis, but unaccompanied by *any marked rise of temperature and pulse* rate and other constitutional evidence of acute inflammation The attacks usually last a few hours only and clear up rapidly, leaving the patient little beyond a sore, bruised feeling locally During the attack and to a less extent for a few days afterwards there is a *fullness and tenderness in the right iliac fossa,* which *is a little* guarded against deep palpation This is due to marked distension of the cæcum, which can be emptied with a definite gurgling sound Between the attacks the existence of a distended, gurgling, and prolapsed cæcum is easily demonstrated, clinically or by X rays

There is no doubt that Wilms s explanation of these attacks is true in a certain proportion but not in all I am sure that in some they are due to limited volvulus of the cæcum the twist being external and the obstruction partial Of this there is distinct evidence in two of my cases (*a*) The cæcum was found large and *freely* mobile, and twisted externally so that the ileo-cæcal valve was situated *antero-externally Fixation of cæcum in its proper* position resulted in a cure (*b*) The cæcum was externally rotated, the retro-cæcal appendix was lying anteriorly, and the terminal ileum passed across the cæcum and appendix to enter the former in its external aspect A Lane s kink was present, somewhat remote *from* the *ileo-cæcal* valve, around which, I think, the *rotation had* taken place A plastic lengthening of the Lane s kink, appendicectomy, and cæcopexy resulted in a cure Lane s kink was present in four of this series and was dealt with in the manner already described, one was further complicated by an extensive Jackson s membrane Two were cured and two were failures, which I shall refer to later A Lane s kink will contribute to inhibitory distension as already shown, and is thus an additional factor in the causation of acute attacks, while these may clearly be accentuated in severity by the pull on a *Jackson s* membrane Operation was undertaken in 18 instances for such acute attacks (1 resembled a gastric *ulcer, and* 17, *acute appendicitis),* the latter figure, therefore, represents 51 per cent of the series Of these 88 per cent were complete cures Two failed to produce complete cure In five instances symptoms were accompanied by vomiting, three were cured

(2) *Chronic right sided dragging pain* —This is a mechanical result *of* the *drag of* an inhibited mobile cæcum and ascending colon on the peritoneum, mesentery, and kidney, and it is associated with varying degrees of right renal mobility (Fig 6) It is this class of case for which nephropexy was so often practised, with such poor results in past years When associated dyspeptic symptoms are present (3) these are attributable to the drag on the terminal ileal and *ileo-colic mesentery, produced* by the *prolapsed* cæcum in the erect posture (Fig 6), and the mechanism is similar to that already referred to in the case of the Lane s kink and the controlling appendix (See Group (3)) Reflex gastro-intestinal inhibition also occurs from the afferent sympathetic stimulus *induced by the drag on the right renal pedicle* It is particularly instructive to note that, whereas in the 21 per cent of cases where chronic dyspeptic symptoms (e g , nausea, flatulence, and distension) were complained of, 85 per cent were cured, when the chief symptom was a right-sided draggin [illegible] 4 per cent) a cure was *only established in 62 per cent , two cases recurring after apparent* cure

(3) *Chronic dyspeptic symptoms* have already been referred to, and may accompany either of the former class of case Cures in 21 per cent of cases were 85 per cent This supports the view that the drag of the bowel stimulated the mesenteric nerves of the ileo-colic *mesentery and (in (2)) the renal pedicle* Further *support* will, I think, be obtained from X ray examination For I have observed that in well marked visceroptosis, where ileal stasis is associated with marked delay in the ascending colon, the peristaltic waves in the terminal ileum are very obvious in the recumbent position, but are *sometimes much less evident and more difficult to follow in the* erect posture I have not, however, examined sufficiently often to be sure on this point It is evident from this analysis that the largest percentage of cures from cæcopexy are obtained either when acute attacks of pain (88 per cent) or chronic dyspeptic *symptoms (85 per cent) are the prominent features*

The smallest percentage of cures result when the operation is undertaken for chronic right-sided dragging pain, and the reason is apparent from a study of the failures

Failures (9 per cent) —In two of the failures present symptoms point to the origin of these as part of a general visceroptosis In one *gastric symptoms* were very well *marked,* and it was evidently a mistake on my part to expect the remedy of an advanced general condition by a purely local procedure like cæcopexy This patient says she is a little better In the other case cæcopexy was only *performed during operation for a supposed recurrent appendicitis*

Recurrences (two cases) —*These* are both *instructive Both complained of chronic right sided dragging* pain in the erect position as the prominent feature In both the cæcum alone was fixed In one case a Lane s kink was remedied, and a cure, lasting for 18 months, was followed by a relapse to the pre-operative condition In the *other* a Lane s kink *was remedied, and a well marked* Jackson s membrane was left untouched cæcopexy only was performed A cure lasted until parturition, when the old symptoms gradually returned, clearly owing to diminished support

Cæcopexy and ascending colopexy —It is interesting to note that in this series the ascending colon was also *fixed in eight cases for all groups of symptoms* One was complicated by gall stones, which I do not think were responsible for the symptoms complained of This operation resulted in 87 5 per cent of cures, one (improved) has occasional attacks of indigestion These figures, small as they are, afford a clear indication of the *reason for these two recurrences* and the means of avoiding them—i e , *if* the prolapsed cæcum is dragging on the ileal mesentery alone the resulting inhibition will cause attacks of acute distension (resembling appendicitis), associated with reflex gastric symptoms of mild or intermittent type (Fig 3) Here cæcopexy is sufficient, and will effect a permanent cure Symptoms associated with right sided dragging are an indication that the right-sided prolapse is more general and is involving the kidney, accordingly, fixation of the ascending colon also is called for (Fig 6) This inference is supported by the good results *of ascending colopexy in the subsequent series,* and when performed as an adjunct to other operations

Constipation —This was a prominent feature in 27 per cent of cases and in these 77 per cent were cured It was not a marked symptom or only present during acute attacks in 72 per cent , and in this series 83 per cent *were cured It would appear that these* were early cases

Reverting to the original total figures for a moment. In the 78·7 per cent. of cases reported in the whole series I find that 5 were complicated by other lesions, which were remedied at the same time. In two a Lane's kink was remedied; one had a controlling appendix, which was removed; one had gall-stones, as already stated; and in one instance I performed a simultaneous suspension of the uterus by shortening the round ligaments in the usual manner. None of these complications materially affect the argument.

Sex.—Finally, it is of interest to note, in view of subsequent remarks, that only three of this series were males, but all were cured.

Before deducing the lessons to be learnt from a study of this series there is one other condition in which cæcopexy and ascending colopexy is called for—namely, when the large intestine is supported by bands attached to the neighbourhood of the gall-bladder. The effect of these bands I believe to be, as already stated, largely mechanical. Their attachment below to the first part of the transverse colon, with its mesocolon, I shall refer to in the next series; but, when they support the cæcum and ascending colon by attachment to their external and antero-external surfaces (a fairly common condition), cæcopexy and ascending colopexy is called for to relieve the drag, and has proved entirely successful.

In one such case the symptoms were extreme constipation (steadily progressive for six years) and chronic dyspepsia of a pronounced type. A Lane's kink was remedied, a normal appendix removed, and the cæcum and ascending colon fixed. The result is a complete cure after nearly four years.

I have already reported 7 cases of mobile cæcum in which no fixation was practised; and in order to strengthen the case, I wrote to 22 patients whose appendices I had removed in past years for supposed chronic appendicitis, and in whom I was doubtful whether kinking, twisting, or other slight lesions of the appendix could satisfactorily account for the symptoms. I received 15 replies: 6 are reported cured (40 per cent.); 4 are reported improved (26 per cent.); 5 are reported in statu quo (33 per cent.). Of the 4 who were improved, in 2 a mobile cæcum was noted but not fixed, and the other 2 still complain of pain in the right iliac fossa. Of the 5 cases reported in statu quo, one has "the same indigestion"; another is under treatment for "duodenal ulcer"; while the third has subsequently proved to have been a case of "enteroptosis," and will be referred to later.

The completion of my evidence is afforded by three cases in the series which deserve special mention—all were females: (*a*) Appendix removed at another hospital—still complaining of pain on the right side. X rays showed marked gastric and ileal stasis. Cæcopexy over five years ago. "Cured." (*b*) Treated for "indigestion," "liver," "ulcer," and "gall-stones" at various times and places. Previous operation for division of adhesions between the stomach and gall-bladder gave no relief. Removal of an apparently healthy appendix and cæcopexy over six years ago. "Cured." (*c*) Dragging pain on the right side, nausea, and dyspeptic symptoms. Appendix removed at another hospital. No relief. Cæcopexy six and a half years ago. "Cured." These three failures added to my own just related are evidence in favour of the value of this simple procedure in properly selected cases.

It is possible that in some few instances a chance cure may result from the formation of post-operative adhesions exactly when they are required, though in the absence of sepsis they are apt to be too filmy and weak to provide the necessary support to relieve tension on the ileo-cæcal mesenteric nerves. Finally, stagnation of contents predisposes to acute appendicitis, which should presumably occur, in a fair proportion of cæca which are inhibited from excessive prolapse. Theoretically, the density of the resulting adhesions should suffice to fix a prolapsed cæcum; and in order to ascertain any possible evidence of this, I wrote to a series of cases in which I had drained the abdomen for acute appendicitis. In practically all drainage was established by one tube to the right kidney pouch and another to the pelvis, after appendicectomy. I received replies from 70 patients. One complained of abdominal pain, one of "bowel trouble," and one of "pain on lifting." The remainder (95·6 per cent.) are cured. It is probable that many of the cæca of these patients were mobile, and the figures contrast favourably with those of the doubtful cases of chronic appendicitis just mentioned. Is this not another small point in favour of fixation of a mobile cæcum?

The main points arising out of a study of these cases appear to be as follows: Mobility of the cæcum and ascending colon is a congenital condition showing a variability only to be expected in a transitional organ undergoing evolution for the purpose of adaptation to the erect position and to food requirements.

Two types are to be noted: (*a*) Mobile cæcum as part of a general mobility of the ascending colon (or transverse colon also) due to failure of the normal process of mesenteric fusion—i.e., a type transitional between complete mobility and perfect fixation. (*b*) Elongated cæcum, when mesenteric fusion is advanced and no signs of general mobility are evident. Here the prolapse is mainly due to an elongation below the ileo-cæcal valve. It is hard to adduce evidence that this is not an acquired condition, though I cannot help leaning towards the view that this is a mild reversion to those types in which the long cæcum and appendix function as a propelling organ for the large intestine. (If fixation be attempted in this group it will be found that there is no room to anchor the cæcum in the iliac fossa, as mesenteric fusion is continued nearly to the pelvic brim. In the few cases I have operated on (and I do not think they are very common) I have fixed the ascending colon also after shunting the whole cæcum and ascending colon upwards, thus allowing room to obtain a retro-peritoneal attachment for the cæcum.)

Cæcum mobile is compatible with perfect health and may never give rise to symptoms. Symptoms are liable to be initiated by any factor tending to increase the normal tension on its mesentery, such primary factors being divided into two groups: (*a*) Diminution of the natural extrinsic supports of a normal viscus; or (*b*) abnormal overloading of a viscus whose extrinsic supports are intact.

Group (*a*) refers, of course, to the support of the abdominal wall and pelvic floor, which may be, and sometimes is, the initial factor in the final descent which gives rise to tension on the mesenteric nerves.

Group (*b*) may arise from any lesion inhibiting the ileo-cæcal area and leading to stasis and overloading (e.g., acute appendicitis, controlling appendix, Lane's kink, &c.). It may arise from general inhibition of the colon, due to more widespread intra-abdominal lesions, mental influence on intestinal activity, dyschezia, &c., the importance of which will be referred to later.

The end-result of both groups is a relative increase in tension in the ileo-cæcal mesentery, consequent active inhibition of the ileo-cæcal area, and the reflex gastro-intestinal inhibition responsible for the symptom-complex already discussed. (Fig. 6.) Thus, a prolapsed cæcum is innocuous until one of these ætiological factors initiates a drag on the mesentery. The extent of the symptoms (*not* the severity) is some indication of the amount of drag caused by the prolapse. On these considerations the indications for treatment are based. Thus, my analysis shows two stages.

(1) *Early prolapse.*—In this stage there is a liability to over-distension from twisting, temporary inhibition, &c., such acute attacks being quickly amenable to treatment in the early stages, but liable to recurrence, especially when associated with a Lane's kink or controlling appendix. In this group the increased mesenteric tension is limited to the ileo-cæcal angle, and constipation is not a prominent feature except in the acute attacks; while reflex dyspeptic symptoms, though sometimes noted, are mild or intermittent. The explanation of the symptoms is analogous to those associated with Lane's kink. (Fig. 6.) In this class of case cæcopexy alone will effect a permanent cure.

(2) *Chronic right-sided dragging pain.*—This may be associated with acute attacks or with marked gastric symptoms. This group is associated with an increased tension on, and stimulation of, the ileo-colic and ileo-cæcal mesenteric nerves (both efferent and afferent). The resulting drag on the kidney further stimulates the afferent sympathetic nerves of the renal pedicle and further contributes towards reflex inhibition; while the same drag is probably responsible for frequency of micturition, especially in the erect posture—i.e., by day. There is therefore a wider area both of efferent and reflex gastro-intestinal inhibition, and these more pronounced and constant symptoms cannot be cured by cæcopexy alone. In such cases the ascending colon must also be fixed, and this is particularly called for if frequency of micturition is a prominent symptom. Nephropexy alone invites failure.

Again, the presence of a well-marked Jackson's membrane is an indication for fixation of the ascending colon as well as the cæcum. For much of the pain is caused by the drag on its attachment to the lateral peritoneum. If this is done the membrane is, of necessity, divided; while recurrence is prevented by the normal fixation of the bowel. Had I done this in my second recurrence I do not think pain would have reappeared from failure of abdominal support after childbirth.

Finally, cæcopexy alone, or combined with ascending colopexy, will only result in a cure (when these are the primary factors concerned) if the effects of secondary inhibition elsewhere—i.e., transverse colon, stomach, &c.—have not resulted in gross changes in these situations which are too far advanced to be remedied by attention to the primary factor only.

I submit that the cure of symptoms in these cases was due to a transference of the pathological strain on the ileo-cæcal and ileo-colic mesenteries (and the renal pedicle) to the innocuous extra-peritoneal tissue of the posterior abdominal wall.

B. *Strain on the Transverse Mesocolon: "General Visceroptosis."*

An increase of tension on the transverse mesocolon may arise from any of the causes of overloading the bowel or a diminution of the abdominal or pelvic support. It may thus be due to secondary inhibition from ileo-cæcal lesions, cæcal prolapse, neglect of defæcation, and a host of other agencies.

The effects are several, amongst the most prominent being: (*a*) Stimulation of efferent mesocolic nerves leading to inhibition of the transverse colon and an increased tension from overloading. (*b*) Stimulation of most of the efferent nerves entering the mesentery of the small intestine, leading to generalised inhibition. (*c*) Stimulation of afferent sympathetic nerves leading to: (1) generalised sympathetic stimulation, with its widespread effects; (2) reflex sympathetic inhibition of the stomach, gall-bladder, &c., which will be considered later.

In this group are 73 cases (naturally of a more severe type) where classical symptoms of marked general visceroptosis were present. (In a very few fixation was only performed to prevent a recurrence of adhesions occurring in undesirable situations.) In all but 11 some form of colopexy was performed, either alone or in conjunction with other procedures.

In these 11 cases, though marked visceroptosis was noted, no fixation was practised for various reasons. The results a varying number of years later are interesting. None report themselves as complete cures; 7 are improved—2 being greatly improved; and in 2 the operation was not a success. In 6 of these cases the operation performed was gastro-enterostomy, which, even in the presence of an obvious pyloric ulcer, does not seem to have cured, but only to have afforded considerable relief.

Fixation, partial or "complete," was performed in 62 cases, of which 2 were operated on comparatively recently, and are therefore of no value in a study of results. Of the remaining 60 fixation cases 2 died—one was the case (already reported) of a little girl with a mesentery to the whole large bowel, on whom I operated during acute obstruction, due to a complete volvulus of the whole intestine, both large and small. This was an emergency operation. The other, whose urine was normal before operation, had a simple fixation performed; the same evening she passed blood in the urine, which became solid with albumin, and she developed a rapid suppression, from which she died three or four days later.

The risk of these fixation operations (as in the cases of the previous group, where there was no death) is therefore negligible.

Five cases cannot be traced to date, and of these one was cured when heard of some time after operation. Five further cases are of rather recent date (i.e., within five or six months), though they can no longer be regarded as convalescent. This leaves me 49 cases, extending over six or seven years, in whom the result of operation can be estimated with fairness. In these 49 cases the operations performed were either: (*a*) Cæcopexy or cæcopexy with ascending colopexy; (*b*) transverse colopexy (Coffey's operation); (*c*) "complete' colopexy (i.e., (a) and (b) combined). These were either the sole procedures adopted (appendicectomy excluded) or formed an adjunct to an operation undertaken for another object (i.e., gall-stones, gastro-enterostomy, &c.).

A general survey of the results shows that of these 49 cases 61 per cent. were cured, 26.5 per cent. were improved considerably, and 12 per cent. were failures. This represents satisfactory results in 87.7 per cent. of cases. I have classed amongst the failures two patients who, from the reports received to date, have improved since the operation (performed 18 months and 2 years ago respectively). But I have classed these as failures because I am not satisfied as to the extent to which the operation is responsible. I shall consider the failures later.

Amongst the cases cured constipation was noted as a pronounced feature in 46.6 per cent., of which adhesions after suppurative appendicitis complicated one, and lesions of the appendix were noted in two. Constipation was very marked in 4 cases and was extremely obstinate in 3. Passage of mucus was complained of in one instance.

Amongst the cases relieved by operation constipation was a prominent feature in 61.5 per cent. Of these, it was very marked in 6 and extremely obstinate in 1; this last was operated on three years ago and now requires no medicine to make her bowels act.

Sex.—It is, again, interesting to note that in this whole series there are only 10 males. Of these 7 had colopexy performed, with 100 per cent. cures.

These figures, however, afford only a general impression, since other factors obscure the results in some of the series. Thus, mesenteric bands from the neighbourhood of the gall-bladder, pylorus, or duodenum to the ascending or first part of the transverse colon were noted in 16 cases associated with—

	Cases		Cases
Lane's kink	2	Duodenal ulcer (to which the band was directly attached)	1
Controlling appendix	1		
Jackson's membrane	3		

In the whole series of 17 cases in which fixation was practised are noted—

	Cases		Cases
Controlling appendix	3	Inflammatory adhesions	2
Jackson's membrane	3*	Appendix removed previously	4
Lane's kink	5		

* Vide supra.

Fixation was combined with gastro-enterostomy in 22 cases (in one of which the gastro-enterostomy had been performed previously), hysterectomy in 1 case, enucleation of uterine fibroids in 1 case, removal of ovarian cyst in 1 case.

Therefore, as a closer analysis is essential to a just estimate of the value of such operations, I propose to subdivide the study of this series into groups.

(a) *Transverse colopexy (Coffey's operation).*—This operation was advocated by Coffey, of Oregon, about 18 years ago, as a means of supporting the prolapsed stomach by forming a "hammock." It is exceedingly simple, and consists of suturing the transverse mesocolon to the anterior abdominal wall. There are a few points of importance to be noted in the operation. 1. To avoid the vessels (and associated nerves) of the mesocolon by using the reverse end of the needle in passing the sutures from above downwards. 2. To take up all the layers of the omentum and mesocolon in the sutures and to place them about midway between the stomach and colon. If unusually redundant the mesocolon may with advantage be pleated in order to obtain a larger surface of attachment. 3. The sutures should be passed at least through peritoneum and fascia of the anterior abdominal wall (not peritoneum only). 4. Distortion should be avoided by placing the sutures from the mesocolon to the anterior abdominal wall in the vertical and transverse planes in which they naturally lie in the recumbent posture, thus forming in the transverse plane a gentle curve downwards from left to right, and corresponding roughly with the direction of the normal transverse colon.

Some seven or eight years ago I had the opportunity, through the kindness of Sir Berkeley Moynihan, of talking to Coffey about his operation and hearing him lecture upon it. His enthusiasm and conviction were responsible for my giving it a trial in a few pronounced cases. Since that time I have practised it alone or combined with right-sided fixation or as an adjunct to other operations. Originally I believed with Coffey that it was a mechanical measure designed to correct a mechanical defect, and I employed it as an attempt to remedy symptoms which Sir Arbuthnot Lane originally described as due to the traction of the colon on the stomach.

Criticisms of Coffey's suspension have, in the main, concentrated on the objection that such a fixation is not permanent, and that the transverse colon again drops in the course of time. This criticism is a perfectly just one in so far as the position of the colon is concerned; indeed, I do not think the operation appreciably raises the colon in the abdomen at all, or, if it does, only to a small extent.

One fact I have verified—namely, that some years after transverse colopexy a pronounced prolapse of the colon may co-exist with a complete cure of the original obstinate constipation. The view as to the purely mechanical object and mechanical effect of this operation I have therefore abandoned; for in what manner can the actual position of the colon in the abdomen, *per se*, influence its proper function, if the neuromuscular mechanism is intact?

On the other hand, I have had an opportunity of verifying the fact that the fixation of the mesocolon to the abdominal wall is permanent, and divides the abdomen into two compartments. One of my cases developed accidental obstruction of the small intestine from a band about a year after transverse colopexy, and I noted that the fixation was in perfect order. He is completely cured to-day.

My next step is to produce evidence to show that the effect of the operation is to relieve the strain on the transverse mesocolon by transferring it largely or entirely on to the anterior abdominal wall, thus removing a constant traction on and consequent stimulation of the nerves issuing from or conducted to the solar plexus (Fig. 7 (B-B′)). If such a stimulation produces direct efferent inhibition of the transverse colon, and, to a less extent, of the small intestine (and a similar reflex inhibition of a widespread character), the removal of such a sympathetic stimulus, by transferring the strain elsewhere, should result both in an improvement in the motor functions of the colon (provided its neuromuscular tissue is not secondarily damaged beyond recovery), as well as a cure of the reflex secondary conditions which may have been established. It is from this point of view rather than any purely mechanical aspect, that I am anxious to submit my results.

FIG. 7.

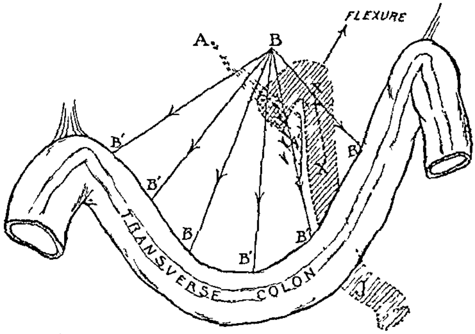

Diagram of efferent inhibition of transverse colon and jejunum in visceroptosis from tension on nerve fibres. A-A, Jejunal inhibition from stimulation of jejunal mesenteric efferent sympathetic fibres. B-B′, Inhibition of colon from similar efferent stimulation. J, Jejunum. X-X′, Area of adhesion of antimesenteric border of jejunum to transverse mesocolon. (Often seen in marked prolapse.)

Analysis of Cases.

Transverse colopexy alone performed.—I have, unfortunately, been unable to trace the records of more than 10 cases in this group, of which the notes of 2 are useless. Of the remaining 8 cases operated on 5 are cured, 2 are improved, and 1 is a failure after seven years. This represents 62.5 per cent. of cures (satisfactory results in 87.5 per cent.) and 12.5 per cent. of failures in this small series.

The failure is of interest. F., aged 31. Suffering from indigestion, heaviness after food, and an extremely obstinate degree of constipation (the bowels acting about once a week). Symptoms were relieved after the operation, and I lost sight of her until recently. In a case of this severity either complete colopexy should have been performed, or possibly intramural damage, whether primary or secondary, was too far advanced for a cure to result from an operation designed against inhibition alone. In any case, apparently, I failed to grasp the full significance of the symptoms.

Two of these cases, I think, are of sufficient value in support of this operation to deserve individual mention.

(A) F., aged 24. Constipation and abdominal pain, severe in character, gradually localising in the right iliac fossa. Repeated vomiting of large amounts. I explored and removed a practically healthy appendix, but found an enormous stomach lying in the pelvis. The appendix incision was closed and a median exposure of the stomach showed no gross lesion. Transverse colopexy established a permanent cure lasting between six and seven years.

(B) F., aged 22. Epigastric pain severe in character, one and a half hours after food. "Heartburn" and "water brash." Lately pain occurs daily and vomiting is increasingly frequent. An apparently healthy retro-cæcal appendix was removed and no definite evidence of ulcer could be seen. Transverse colopexy only performed, six and a half years ago. She is cured up to the present time.

Of these 8 cases, gastric symptoms were prominent features in all but only very severe in 3 cases. Constipation was a marked feature in 4, of whom 3 were cured. Where bands to the stomach or gall-bladder were noted they were lengthened in the usual manner.

I cannot help feeling it very difficult to attribute the cures in this series to any factor other than the removal of pathological nerve impulses which were disturbing the normal mechanism. On no other grounds that are evident can the improvement in the motor functions of the colon be explained by this operation in those patients who were constipated, particularly when the actual position of the large bowel in the abdomen—in the majority at least—is not materially altered. The severe gastric symptoms in the two cases reported were clearly due to reflex inhibition and pyloric closure. Can the complete cure of these be satisfactorily explained on other grounds than the removal of a pathological reflex? I have looked carefully in all cases for evidence of mechanical traction on the stomach (as evidenced by mesenteric bands, &c.). These are present in the minority of cases only. It cannot surely be held that a powerful viscus like the stomach can be so extensively impaired by a small degree of mechanical traction. Only on two occasions have I observed bands directly attached to the scar of an ulcer.

It is clear that fixation of the transverse mesocolon is of limited value if the reflex inhibition of the stomach arises primarily from an ileo-cæcal (or ileo-colic) stimulus. In this event improvement might possibly result from removing a secondary (or adjuvant) cause of such reflex inhibition, even if a cure did not result. This oversight may have accounted for the two patients who were improved and received definite benefit from the operation, but whom I did not feel justified in classing as cured. It may also have accounted for the failure.

An analysis of the failures in both right-sided and transverse fixation seems to suggest that in a certain proportion of the severer cases undue tension on both ileo-colic mesentery and transverse mesocolon was jointly responsible for the generalised symptoms.

Thus, in one case improved by ascending colopexy in this series there is no doubt that I failed to obtain a complete cure by omitting to combine transverse colopexy. On the other hand, in another instance the gastric symptoms were pronounced enough to have twice given rise to a diagnosis of leaking ulcer by unquestioned authorities. In this case bands from the gall-bladder, pylorus, and duodenum supported the cæcum and ascending colon, and led me to fix the cæcum and ascending colon. At the same time the extreme severity of the gastric symptoms induced me (even in the absence of an evident ulcer) to perform gastro-enterostomy. This patient is completely cured, over two years later, but I am not convinced that a fixation alone would not have achieved a similar result.

I have analysed these results as impartially as I can, and the definite proportion of failures or partial successes has only confirmed my conviction that there is a more severe class where symptoms are caused both by ileo-colic and meso-colic tension combined. In this group the prominence, duration, and constancy of gastric or dyspeptic symptoms (associated with varying degrees of constipation) indicated the advisability of "complete colopexy."

(*b*) *Complete colopexy.*—This consists in a combination of Coffey's transverse colopexy with cæcopexy alone or together with ascending colopexy. There are 22 cases in this series, of which 4 are too recent to be of statistical value. In the majority severe gastric symptoms were the outstanding complaint. I have therefore a series of 18 cases in which the late results are known. Of these 55·5 per cent. are cured, 33 per cent. are improved, and 11 per cent. represents the failures.

Of those improved 2 are so greatly improved as to be practically cured; and I think I should be justified in including them in this class. This would give the following figures: Cured, 66·6 per cent.; 22·2 per cent. improved; or satisfactory results in 88·8 per cent. of cases.

Of the failures, 1 (a girl of 25 years) was constipated to an extraordinary degree, medicines being described as "useless." The operation was only performed two years ago, and I am informed that she is not cured, but that the bowels now act with medicine. I still think there is hope of a cure in this case with time and perseverance.

The second failure is of sufficient interest to be reported in detail.

F., aged 24 (neurotic). Complaining of pain, dyspepsia, nausea, &c., and frequent vomiting. Prolapse of very dilated stomach and large bowel to an extraordinary degree. Her condition was pitiable. Appendicectomy and complete colopexy was performed six years ago. Symptoms were completely relieved, and there was a marked gain in weight and improvement in general conditions. This patient some time after convalescence nursed a sick relative and got run down and tired. Some months later she wrote that she was worse. Since then I have not been able to trace her, but I think this may be an instance of a failure to appreciate the primary factor as psychical. (See Mental Factor.)

Of the cases cured, 2 were complicated by the removal of gall-stones, which seem to have been responsible for symptoms in only 1, a girl of 16 years. In this child 52 gall-stones were removed and complete colopexy was performed, as practically all the large bowel had a long mesentery, the prolapse being extreme. The cure is complete.

In one 11 uterine fibroids were also enucleated and a grossly diseased appendix removed. The appendicectomy probably contributed towards the final cure. Jackson's membrane was well marked in one case.

In this series of cures there is one case of unusual interest.

F., aged 31. "Gastric trouble" for 16 years. Acute epigastric pain, indigestion, and frequent vomiting. Attacks of hæmatemesis. Repeated and persistent courses of medical treatment resulted only in temporary abatement of symptoms, and were invariably followed by recurrence. At operation no gross lesions of the stomach could be found. Complete colopexy was performed seven years ago, and she is cured up to the present time.

Flatulence, distension, nausea, or lassitude were complained of in 66·6 per cent. of cases (1 case of gall-stones excluded), and of these 91 per cent. were cured or definitely relieved in approximately equal proportion. Where such symptoms were absent (6 cases) 5 were cured and 1 is probably a failure (the case of pronounced constipation already reported). Vomiting was an outstanding feature in 5 cases, of which 3 were cured and 1 relieved. Pain (with vomiting as an occasional or frequent accompaniment) was marked in 10 cases—7 were cured, 2 relieved, and 1 was not benefited by operation. Of this 70 per cent. of cures in 1 gall-stones were removed, though symptoms were quite atypical. In 1 the pain was a left-sided "drag." One simulated attacks of acute appendicitis. In 2 the pain was epigastric, and in 2 it simulated gall-stone colic. Constipation was a prominent feature in 10 of the cases in this series (55 per cent.). Of those so affected, 5 are now cured, 4 are improved, and 1 so far is not successful. Of those cured, constipation was pronounced in 3 cases; and in 2 it was extremely obstinate. Of the 4 cases improved, constipation was obstinate in all. In the 1 case classed as a failure (already reported) constipation was very obstinate, but appears to be very slowly improving. Frequency of micturition was a symptom in 6 cases, in 5 by day only, and in 1 both day and night. All were either cured or improved.

There is one feature in this series to which attention may be drawn—namely, the proportion of constipated patients cured or relieved. If the normal action of the colon depends in any way on its actual position in the abdomen these operations cannot have exerted any material influence. For the position of the transverse colon, as a rule, is not materially altered; or, if it is, such an alteration is often not permanent. If, however, the driving power of the colon is diminished through an undue domination of impulses in one group of its dual nerve-supply (through constant, though possibly slight, mechanical stimulation) the removal or abatement of such a factor may result in steady improvement.

Again, I trust I am not biased in concluding that this series affords further support to the view that such a mechanical stimulus can be diminished, or removed, by transferring the mesenteric strain to a region where it is comparatively innocuous. Such, I suggest, is the object, not only of transverse colopexy, but of ascending colopexy also.

The Effect of Active Inhibition on the Gall-bladder, Stomach, Pancreas, &c.

Gall-bladder.—When the abdomen is opened in a well-marked case of visceroptosis, there is one feature which has often struck me, and must often have appealed to others—namely, the marked distension of the gall-bladder in the great majority of instances. The gall-bladder appears thin, bluish, distended, and firm to touch; and it is difficult to empty by steady pressure. When there are obvious bands attached to the fundus, or neck of the gall-bladder, or to the cystic duct, such a distension is easily explicable on mechanical grounds. But in the majority there are no such features to be observed.

The gall-bladder being an outgrowth from the alimentary canal, is innervated in the same manner, as recently emphasised by Langdon Brown. If, therefore, abnormal mesenteric tension elsewhere is causing reflex sympathetic stimuli in various parts of the intestinal tract, it is not surprising that a resultant inhibition should involve the gall-bladder. On these grounds I have regarded marked distension of a gall-bladder, which is free from adhesions and shows no other signs of inflammation, as evidence of active reflex inhibition from some remote mesenteric stimulus; in visceroptosis it may perhaps be an indication that this condition is exerting pathological effects. Further, in cases where gastric stasis is well marked under X ray examination it will usually be observed that the gall-bladder exhibits the features referred to.

If such an inhibitory stasis renders the gall-bladder unable adequately to empty itself of bile, such a stagnation may be an important ætiological factor in the development of gall-stones; and it is not difficult, from such an aspect, to appreciate the frequent association of gall-stones with ileo-cæcal or ileo-colic inhibition. Again, Moynihan has laid stress on the association of gall-stones (even in the absence of any typical symptoms), with flatulence, indigestion, and other gastric symptoms. It is not difficult to appreciate that the original source of the gall-bladder inhibition (possibly a contributory factor to the formation of calculi) may equally have exerted its reflex inhibition on the stomach and be responsible for such symptoms.

Such a view would not only account for the occasional coexistence of gall-stones with gastric or duodenal ulcer, but would lead one to expect that cholecystitis, with or without calculi, would not infrequently be associated with visceroptosis—such experience as I have had has confirmed this expectation in a very fair proportion of cases; though the calculi have not always been responsible for the symptoms.

Probably most of us have seen patients, the subjects of definite visceroptosis, complaining of many of the symptoms of gall-stones, who, on exploration, were found to have the distended gall-bladder referred to, but no gall-stones. In several instances in my series such symptoms were completely relieved by colopexy.

Gastric and Pancreatic Inhibition.

There is reason to believe that the musculature of the pyloric part of the stomach has an analogous innervation to the small intestine; the cardiac half is probably supplied by the vagus alone both for contractile and inhibitory purposes. The pathological conditions we have been discussing as responsible for direct or reflex sympathetic stimulation, will, in the case of the stomach, only affect the pyloric part. The stimulation of the efferent vagus (by the afferent vagus impulses already referred to) results in a contraction of all the muscles of the cardiac end and fundus of the stomach. The contraction of the circular and longitudinal fibres diminishes the lumen, and thus tends to force the food into the pyloric end; a function further assisted by the raising of the fundus effected by the contraction of the oblique fibres. The food, thus forced into the pyloric end by these rhythmic waves, excites the mechanical pressure stimulus which initiates the peristaltic wave (consisting of contraction and concomitant inhibition). The peristaltic waves are responsible for driving the contents towards the pylorus in a manner analogous to that seen in the intestine. The relaxation of the pyloric sphincter is due to the presence of alkaline pancreatic secretion in the duodenum, the presence of acid gastric chyme being responsible for the closure of the sphincter until its neutralisation by the former allows a further relaxation.

A reflex stimulation of the sympathetic from the various lesions under discussion will inhibit the peristaltic waves to some extent and prolong the pyloric closure, while leaving unaffected the cardiac end and fundus (not inhibited by the sympathetic). Such a stimulus further excites a constant increase of adrenal secretion above the normal, which may also contribute to prolonged pyloric closure; a feature which may further be accentuated by a consequent deficiency in pancreatic secretion, due either to excessive adrenal secretion or to insufficient acid chyme in the duodenum. The possible importance of this last factor in the ætiology of congenital hypertrophic pyloric stenosis in infants, as well as in the causation of the added spasm (often responsible for completing the obstruction), was recently emphasised by Dr. G. R. Pirie, and applied by us both in a clinical study of this condition. If our deductions are correct one may, perhaps, infer that the same cycle of events obtains in the case of adults, the only difference being the *degree* of obstruction possible from such causes in a normal adult pylorus.

Such a prolonged reflex closure of the pylorus (with inhibition of the pyloric half of the stomach) will, if excessive, constitute an intermittent pyloric obstruction of varying degree, which, as in the case of the intestine (Bayliss and Starling), will increase the rhythmic waves behind. These features are observable under X ray examination, for in this class of gastric stasis the waves, which are usually seen to commence in the distal half of the stomach only, may often be observed almost at the cardiac end in extreme cases.

It is evident that under these conditions of reflex inhibition we have some at least of the necessary factors for the establishment of gastric stasis, hyperchlorhydria, &c., consequent on obscure lesions elsewhere. For if the glands of the cardiac end (like the musculature) are not supplied with sympathetic inhibitory fibres their *secretion would not be inhibited* Such may be the explanation of the large splashing stomach which is such a constant feature, while the associated hyperchlorhydria may be due to the continued secretion (by the oxyntic cells in this region) of hydrochloric acid which cannot escape into the duodenum at the normal rate

That these conditions could be modified or relieved if such an inhibitory stimulus were removed is clear, and I suggest that the modification or cure of the gastric symptoms in the series just studied, by the various *forms of colopexy performed*, is due to the removal of such a mechanical nerve stimulation

Gastro enterostomy and Colopexy Combined

In cases of long duration constant spasm of muscle may lead in the course of time to some degree of hypertrophy, so that, while *the removal of an inhibitory* stimulus *may cure the condition in* comparatively early cases, such a result may not be attained if the condition has been progressive for some time and secondary factors are established It is clear that, in the varying degrees of gastritis, consequent on a retention of contents we have at least one of the ætiological factors in ulcer formation, particularly if the element of prolonged sepsis be added

Thus Dr Pirie and I inferred that pancreatic functions do not recover *immediately if they have long been in abeyance And it is* possible that some degree of pyloric hypertrophy, with a spasm accentuated by pancreatic insufficiency, may persist after the *original exciting cause has been removed—in fact, a secondary* ' vicious circle may become established

That this is one of the causes of failure in the foregoing series I am confident How, then is the pancreatic function to be re established and the normal pyloric relaxation ensured? This can be effected by gastro enterostomy which allows *acid chyme to leave* the stomach by the stoma, and stimulate prosecretin to form secretin Secretin, reaching the pancreas by the blood stream, *stimulates the pancreas to pour its alkaline secretion into the* duodenum (Bayliss and Starling), thereby ensuring the normal pyloric relaxation by establishing duodenal alkalinity When this end is *effected, food* will pass by the normal route rather than by the artificial stoma—a most desirable objective—and normal functions will be restored

Criticism of this procedure has been justly based on the poor results obtained when there is no gross obstruction, but the reasons *for failure have, I believe not been fully appreciated A discussion* on this subject may well form a study in itself but, from the point of view of inhibition alone, it seems clear that if gastro-enterostomy *alone is performed, the pyloric spasm is unaffected, because* the ' fons et origo ' is overlooked

Again, the artificial stoma (if the posterior no loop anastomosis is practised) does not function, because, in the upright posture, the prolapsed colon and stomach, dragging upon the upper jejunum and its mesentery, *stimulate mechanically its efferent* sympathetic supply, and thus inhibit partially or completely its muscular action This ballooning of the jejunum can be well observed *when* gastro-enterostomy is performed under spinal anæsthesia (Fig 7 (A-A')) Therefore the jejunum being inhibited, chyme does not leave readily by the stoma, pancreatic insufficiency is not corrected, pyloric spasm persists, and symptoms are unrelieved If such a jejunal inhibition is excessive the bowel becomes "water *logged*" (just as Moynihan *demonstrated to occur from axial* rota tion) May this not constitute one of the causes of "vicious circle" after gastro-enterostomy?

Again, a membranous adhesion of the first ½ in to 1 in of the antimesenteric border of the jejunum to the under surface of the mesocolon is often present in *visceroptosis (Fig 7, (X-X'))* This has been emphasised by Mayo If my contention be accepted—namely, that kinks rarely produce mechanical obstruction—is not the *elongation and distension of the duodenum (so commonly seen)* primarily a natural sequence of direct jejunal inhibition? Again, in pyloric and duodenal ulcer, for example, the hunger pain is attributable to the return of the pylorus to its state of firm closure when the stomach is empty Such a closure takes place onto an ulcerated surface—a condition which *obviously prevents healing*

Many such ulcers produce no organic obstruction, yet they will often heal after gastro-enterostomy! Is it not a logical inference that *pyloric spasm is accentuated by* pancreatic insufficiency, which can be remedied by allowing the acid chyme to pass by the artificial route—i e, the gastro-enterostomy stoma? Evidence goes to prove that pyloric relaxation obtained by this mechanism is responsible for the healing of pyloric and duodenal ulcers after gastro-*enterostomy, but this is only complete if every cause of pyloric* spasm and potential jejunal inhibition is remedied simultaneously Is not the failure to remedy associated causes of reflex pyloric closure *and potential* jejunal inhibition responsible not only for the partial successes following gastro enterostomy but for failure of gastro-enterostomy when prolapse is marked? *For if relief of* pylorospasm in the presence of an ulcer can be achieved by gastro-enterostomy, why not expect equal efficiency when no ulcer exists?

If my deductions are correct, it would be expected that combined colopexy and gastro-enterostomy would *not only relieve the reflex pyloric closures and pyloric inhibition but would also prevent* jejunal inhibition That this is so I hope to establish by a study of *my* next group of cases *Here the prolonged and constant* symptoms were pre eminently referred to the stomach and were taken as an indication that though the primary cause must be looked for and remedied, secondary gastric and pancreatic sequelæ were too far advanced to be remedied without more extensive measures

In this more advanced class of case the combination of predominant gastric symptoms, marked stasis contracting waves starting at the cardiac end, together with a pylorus which at operation appeared in most instances to be definitely thicker than normal (*I freely admit the difficulty of being positive on such a* point), led me to perform gastro-enterostomy (posterior vertical no-loop) combined with either transverse or complete colopexy

There are 24 cases in *this series*, of which 3 are too recent to be of definite value In this series again there was no mortality Of these 21 cases, 15 are cured (71 4 per cent), of which 1 cannot be traced, but was quite well some time after operation, 4 cases (19 per cent) are improved by the operation, 2 cases (9 per cent) failed This represents 90 4 per cent of satisfactory results in some years practically all having been traced to date Of the two failures, one is relieved of the gastric symptoms, but the result is complicated by uterine and other troubles (I am not at all sure that I was not mistaken here as to the chief complaint requiring attention) In *the other failure the girl was a marked neurasthenic* and had been under treatment for this condition I was of opinion that the gastro intestinal symptoms were largely the cause of the neurasthenia this view has proved incorrect I *feel* sure in this instance I did not recognise the type of gastric symptoms stasis pain, &c, as belonging to a group which I shall refer to later as rarely suitable for surgical interference (See "Mental Factor") Of the 4 relieved, 2 are greatly relieved, and may almost be classed in the first *group Had I not wished to err on the side of* caution I might with some justification have given these figures as 81 per cent, 9 per cent, and 9 per cent, respectively

Ulcer—A most careful search for external (peritoneal) evidence of an ulcer was made in all cases Of those cured, such evidence was only found in 2 cases Hæmatemesis without visible ulceration *was noted in 1 case Of those relieved, evidence of an ulcer* was seen in 2 cases No evidence of ulcer was seen in the two failures

The operations performed were —

Gastro enterostomy and complete colopexy			16 cases
,,	,, transverse	,,	4 ,,
,,	,, ascending	,,	1 case

(In the last case ascending colopexy was combined in order to relieve the *tension on bands from the gall bladder and pylorus* which were supporting a mobile cæcum and ascending colon A complete cure resulted)

Pain was severe in 16 (76 per cent), of which 81 per cent were cured and 12 per cent relieved When no acute pain was com plained of (5 cases), 4 were cured of their symptoms Vomiting was *a marked feature in 9 cases (42 per cent) When it was an* accom paniment of acute pain (7 cases) 6 were cured and 1 was relieved Constipation was noted in *50 per cent it was severe in 33 per cent* of these When constipation was prominent, 53 per cent were cured and 36 per cent improved When no constipation is noted, there are 10 *per cent of failures* and 80 per cent of cures

Many of these cases are very instructive but I will only quote one example, the case of a lady of 48 with a history of painless hæmatemesis 14 years previously Operation was advised and declined She had suffered from ' poor digestion for years, with pain and *discomfort, never acute* She was a *woman of poor* physique, sallow and wasted Two years ago there was another hæmorrhage and she consulted a surgeon, who explored and, find *ing no ulcer, divided a band* Since then pain became progressively severe and acute, and a year later I saw her She had a most pro nounced visceroptosis On exploration the colon was found to have practically no fixed points An extra-cæcal appendix was removed No ulcer was found, but the marked gastric history induced me *to perform gastro enterostomy Complete colopexy* was also performed Though it is only seven months since the operation she has never felt so well for years, has put on weight, and considers herself well There is no question of the results being transitory, for some of the cases were operated on many years ago If the figures given be contrasted with the *late results* of gastro-enterostomy alone, I cannot but infer that they support my hypothesis

Only the other day I had the *opportunity of* seeing two of these patients on the same day, and the contrast was worthy of note Previous to operation both had markedly enlarged, prolapsed, splashing stomachs (one also had an ulcer on the lesser curvature at the cardiac end), and general visceroptosis to a marked degree Both were chronic dyspeptics of several years *duration The man* had a gastro-enterostomy performed with no fixation about five and a half years ago the woman had a gastro-enterostomy and complete *fixation five months ago The former still takes bismuth (though* describing himself as much improved), and has the same large splashing stomach some hours after food the latter has no trace of gastric dilatation or splashing on examination

Again, I find the notes of five cases where gastro-enterostomy alone was performed in *past years for symptoms of ulcer in the* presence of marked visceroptosis In one partial pyloric obstruc tion from long standing obvious ulceration was present *This patient is very greatly* relieved, but still has slight indigestion nearly three years later None describe themselves as cured and one was certainly a failure *Is there not sufficient justification for the* belief that these five cases might have been cured by a combined colopexy? I think that there is considerable evidence to show that the *relief of mesenteric* strain is an important adjunct to gastro-enterostomy where this operation is indicated in long standing or advanced cases

I admit freely that none of the evidence is conclusive, much is, of necessity indirect and I could have wished to present a larger series for analysis, but, such *as it is not only does it seem to support* the principles on which the treatment of these cases was based, but the results appear also to afford justification *for the procedure adopted*

As a summary to the whole series of cases studied, I submit that the pathological effects of increased mesenteric tension are not only *confirmed* by a study of symptoms but that this hypothesis is further supported by the beneficial results of relieving such tension by the various fixation operations discussed

Gastro intestinal Inhibition from Extra abdominal Causes.

Space only permits *a brief reference to some* examples which are of importance from the surgical aspect I lay some stress on them because I believe the failure to appre ciate fully some of these obscure factors has been responsible for the unsuccessful results in some of my cases

(a) *Mental factor*—It is doubtful if this can be exaggerated Cannon and Crile have *both* emphasised the *effect of violent* emotions on the splanchnic system in animals; and their observations have been applied clinically by many. Over a prolonged period of time a summation of small stimuli may equal in effect the results of one short sharp stimulus. Thus, the effect of short-lived rage, fear, or other powerful emotion is analogous in its results with that of anxiety, grief, prolonged mental strain, unhappiness, overwork, &c. Amongst the latter class must be grouped abnormal mental impulses of the neurotic and neurasthenic subjects. Such patients are frequently the subjects of gastro-intestinal disorders of varying degree; and the difficulty is to determine whether the neurosis is primary or secondary to prolonged intestinal derangement. In common with others, I have had the gratifying experience of curing a supposed neurotic subject by operation; but, on the other hand, I have certainly made the reverse mistake, as I have shown. In the series of complete colopexies there is one case which I have classed as improved with considerable hesitation. She is definitely improved in some respects, but comes of a family with a bad mental history. The operation was only undertaken after prolonged consideration, but I am not certain how far it has been justified by the result. Many of these subjects show marked gastroptosis and prolapse of the colon, together with gastric and intestinal stasis; and in many respects they resemble the cases just studied.

The prolonged and excessive sympathetic stimuli of mental origin might well be held responsible for producing gastro-intestinal inhibition in an analogous manner to those just studied; but I am tempted to suggest that the pathology is a little different in some respects. Thus prolonged mental excitement is characterised by an excessive stimulation of the sympathetic system, and Langdon Brown emphasised the probability that secretory inhibition, marked in the case of the salivary glands, was true, to some extent, in the case of other secretory glands. We know that such stimuli provoke excessive secretion of the suprarenal medulla. (Elliott.) Is it not possible that this last factor is responsible for primary inhibition of pancreatic functions? If so, and the previous suggestion as to the probable responsibility of pancreatic engorgement for the sensation of hunger is correct, have we not an explanation of loss of appetite in this class of patient?

The deficiency of the resulting afferent vagus stimulus will elicit a poor vagus response. Thus, constipation might well result partly from a different primary cause—namely, deficient rhythmic waves leading to delayed excitation of peristalsis. In the case of the stomach, though prolapse and gastric stasis are present, a deficient vagus efferent stimulus will be characterised by feeble gastric contractions, *in marked contradistinction to the accentuated waves of* contraction noted in the series just studied. Coincidently a deficient gastric secretion, with a marked decrease in hydrochloric acid content (so characteristic of these patients), is similarly explained; and these features contrast again with those noted in the previous class of dyspepsia. In support of this I have noticed at X ray examinations that in nervous patients and where the meal is distasteful the feeble gastric movements are frequently succeeded by vigorous contractions, as mental reassurance is re-established or the distaste subsides.

Though I cannot speak with conviction from a limited experience, I may, perhaps, suggest that this distinction may be an *important point in eliminating the primary psychical factor.* I cannot help feeling that some failures might have been avoided in the past had more attention been paid to this point, though alone it *could not be conclusive.*

At the same time the possibility must not be overlooked that such continued and excessive abnormal sympathetic impulses may, in the course of time, lead to gross secondary changes of a similar character to those already studied For the relief of these surgical intervention may be necessary in spite of their psychical origin.

(*b*) *Sex.*—Though many factors have been considered as responsible for initiating pathological processes in the subjects of visceroptosis, the marked preponderance in females, as well as the larger proportion of post-operative cures in males, are not entirely accounted for on anatomical grounds alone. Thus, even in male infants Dr. Pirie and I believed we could trace a definite influence on the gastro-intestinal tract of pathological stimuli arising from the prepuce; while I have often noted the improvement in mild *constipation and vomiting in breast-fed babies after a necessary* circumcision when no other treatment was adopted. A striking example came under my notice about eight months ago—a male infant (one of twins, the other child being a girl), a fortnight old. Progressive vomiting and constipation of a week's duration had led to rapid wasting. Visible gastric peristalsis was extremely marked and a large palpable tumour was easily demonstrated. Phimosis of a considerable degree indicated the wisdom of *circumcision, after* which vomiting ceased and constipation disappeared. To-day both are beautiful children. The girl never showed any symptoms. If it be remembered that the propagation of a race depends on the integrity of such reflexes (amongst the most powerful impulses in the animal kingdom), is it not reasonable to infer that even a small lesion may sometimes initiate appreciable remote sympathetic effects? I only refer to this type of case in support of the view that such local lesions may be of considerable importance; *and that* equally the psychological aspect of this question may be an accessory factor in sex incidence. This, however, forms a complete subject of its own, and is clearly outside the scope of the present study.

(*c*) *Dyschezia* in all its forms, deficient rectal sensation, neglect of the call to defæcation, &c., all fully dealt with by Hurst, need not be discussed beyond saying that all may be the primary cause of overloading of the colon and may be responsible for starting the cycle of events culminating in widespread gastro-intestinal inhibition. It is obvious that correct and prompt palliative treatment of such conditions may effect a cure, but not alone if secondary factors (such as increased mesenteric tension) are firmly established.

(*d*) *Enterospasm.*—We have considered in some detail sympathetic stimulation and the resulting intestinal inhibition; but there is one condition where, it appears, the nerve balance may be deranged in the reverse direction. Thus, if the sympathetic be paralysed, normal inhibition is eliminated and vagus impulses exert unchecked domination. The result is disordered intestinal contraction ("enterospasm"), which is a definite cause of constipation. That the sympathetic system is influenced by nicotine is well known, and accordingly enterospasm is sometimes associated with oversmoking. (Hurst.)

There is one case in my series where I removed the appendix under the mistaken impression that it was responsible for symptoms. For some years symptoms continued as before, but cleared up on the patient leaving off smoking.

I now propose to refer briefly to certain types of disorders where the motor function of the intestine is impaired owing to disease of the neuromuscular tissue itself.

Intramural Lesions.

These may be diffuse or local, and, once more, the large bowel is principally involved.

Diffuse or generalised intramural disease.—Professor Keith has shown that in some cases, at any rate, where the colon had been removed Auerbach's plexus had been damaged beyond repair. It is clear that if fibrosis has replaced muscle or nerve and the bowel wall is incapable of responding to normal reflexes, there is only one remedial procedure—i.e., resection of the grossly affected part.

The clinical difficulty is to know when power of recovery is present.

There are two classes in this group according to the origin: (*a*) primary bacterial infection from within, leading to permanent neuromuscular damage; and (*b*) primary inhibition, leading to stasis, chronic inflammation, and similar effects.

Thus, in Group (*b*) the inhibitory factor discussed may, if unremedied, lead to the same end-result as in Group (*a*), which may arise from any prolonged or repeated bacterial infection of the colon—e.g., from dysentery (as in at least three of my cases), prolonged colitis (two cases), &c.

In one case recently operated on, obstinate constipation, progressive for over 30 years, dated from very severe enteric fever in childhood. This is one of the worst cases I have ever seen, both from the local and general point of view. A week after resection the bowels acted without medicine once or twice a day, and her thyroid enlargement had practically disappeared. In both these groups the end-result is the same, and the treatment depends on the difficult decision as to the degree of recovery possible. Some years ago I based such a decision on the presence of massive, putty-like fæcal contents in the cæcum and ascending colon after evacuation of the bowels. I looked on this as a sign of gross *impairment to the muscle itself, and one of the indications for* resection. I now believe that such a decision cannot be based on purely local signs, owing to the extraordinary power of recovery evident on occasion (particularly in young subjects) when the colon is diseased primarily from external causes (Group (*b*)); and also from the difficulty of estimating this clinically.

On clinical grounds and from X ray examination it would appear that the end of the transverse colon and the descending colon are seldom if ever in such an advanced state of disease as to require resection. Even if disease is advanced it is a region fairly accessible to palliative treatment, as is the pelvic colon. It must very rarely be necessary, therefore, to resect the whole colon. I have resected as far as half (occasionally two-thirds) of the transverse colon, from the terminal 6-12 inches of the ileum, in 31 cases during the last five years (Friedrich's operation). The ileum was anastomosed to the remaining part of the transverse colon. This operation leaves little if any raw surface afterwards, and is much less severe than complete colectomy; further, it is doubtful if the results are inferior. Several cases in this series had had more than one operation previously. In one case hysterectomy had been done ten years previously; the transverse colon anastomosed to the pelvic colon eight years previously, adhesions were divided for partial obstruction one and four years later by different surgeons, and she had visible peristalsis when I operated in 1919. I had to resect the terminal ileum and the proximal two-thirds of the colon, including part of the pelvic colon at the site of the anastomosis, where the transverse colon was enormously distended by a massive collection of fæcal contents. The result to-day is very satisfactory. I mention this case to emphasise that many of the patients in this group were in poor condition from long illness; also, the various pathological conditions being more advanced, the risk is naturally increased. The mortality in these cases was 20 per cent. from all causes. Two supposed to be out of danger died on the tenth day from pulmonary embolism, and one (a very severe case of colitis) from generalised hæmorrhages from almost every mucous membrane (probably of acute infective origin from the bowel). Of the remaining 3 there are good reasons for believing that 2 should not have been lost. I think the maximum risk may justly be estimated at about 10 per cent. Nevertheless, this risk alone is sufficient to reserve it for those who are practically chronic invalids.

In this series of 24 cases 2 cannot be traced, 36 per cent. are cured, and 41 per cent. are improved considerably. In 22 per cent. the operation was of no real benefit, though improvement was noted in some respects. In 3 of this series the operation was performed for obstinate colitis, and in 2 when progressive symptoms had dated from dysentery. Seventeen cases were operated on for constipation, and the most striking results were obtained when this symptom, with its sequelæ, was most distressing. Pronounced coloptosis was a feature in all but two, who were suffering from severe chronic colitis.

A review of this series has brought out several points of interest. In the first place 36 per cent. of complete cures seems a small figure when balanced against the risk of the operation, and I think this is so even if 41 per cent. are considerably improved. When successful the results have usually been strikingly good; while among those classed as improved, complaints of occasional flatulence, attacks of pain, or recurrence of constipation in mild degree, are sometimes to be balanced against the relief of the original symptoms. Again, where secondary gastric symptoms have been *pronounced, these have sometimes been improved, but* not always cured, by resection (presumably because they were too *firmly established to be cured by attention to the primary factor* alone). Finally, there are a few cases in this series which I think might have been cured by less drastic measures (of the type already considered) especially when the intramural degeneration was apparently secondary to inhibitory stasis

Against these observations must be balanced the distressing picture presented by *some of these patients* when *every form of* treatment has been tried without benefit The hopelessness of the outlook in a steady progress from bad to worse cannot but be justification for a measure of considerable risk if there is a *prospect of 35 per cent cures or 77 per cent* satisfactory results Accordingly I think this operation has a very definite place in the surgery of very advanced stasis and offers a good prospect of cure or improvement

But I am equally convinced that it should only be performed when it is certain that the bowel wall is diseased beyond hope of recovery This point cannot be determined on local evidence *at exploration alone more certain indications* being the age duration and progress of symptoms and the degree of suffering These combined with the appreciation of the original cause and a careful estimate by X rays of the extent of impairment of motor functions, will probably ensure that resection is only practised when there is no other chance of cure Finally in cases of doubt the origin of the symptoms from definite intestinal infection is a point *in favour of resection for then the neuro-muscular* tissue is primarily unpaired

Localised Intramural Lesions

Colic and intussusception —Colicky pain is essentially associated with intestinal movements and is absent while the intestine is at rest Since the *bowel wall is insensitive it would seem to* be a corollary that such pain is produced by an increase of the normal mesenteric tension during a peristaltic wave Intramural lesions *whether inflammatory or neoplasms must inhibit directly the mechanism of the bowel wall* so that an *inert area* or *segment* is produced which cannot respond to the normal inhibition of a peristaltic wave As a result the contracting segment of a peristaltic wave tends to drive such an inert area onwards into the lumen of the gut an event which is only prevented by the anchorage of the mesentery The pull on the mesentery originates this pain That this is so is seen in the occasional tendency to the formation of intussusception in annular carcinoma the elasticity and length of the mesentery being the determining factor

Intussusception —The determining factor in the causation being the elasticity and length of the mesentery there are I believe two main exciting causes of intussusception (1) those within the lumen of the bowel and (2) those affecting the bowel wall itself

1 In this group are classed such causes as intestinal polyps and *invaginated Meckel s diverticulum &c But the* common cause is swelling of the lymphoid tissue of Peyer s patches in the lower ileum associated with errors of diet Such œdematous swellings project into the lumen of the bowel in an analogous manner to its contents On the passage of a rhythmic wave over such a point the pressure stimulus is excited and the resulting peristaltic wave drives it onwards the bowel wall being dragged in after It is *noticeable that intussusceptions of dietary origin are usually of the* ileo-colic type

2 There is however a smaller group of intussusceptions not capable of such an *explanation* and *this group* more *especially* concerns this study I have elsewhere shown that there is evidence that some acute infections (e g acute rheumatism) which produce effusions into various structures such as skin pleura pericardium &c, may also invade the intestinal wall On occasion such an effusion may be large enough to form a palpable tumour and rupture the mucous membrane resulting in hæmorrhage from the bowel *This is known as Henoch s purpura I have seen* a similar condition mistaken for intussusception in an infant suffering from diphtheria Such inflammatory intramural lesions must inhibit directly a definite area of bowel wall and when reached by a *peristaltic* wave prevent the normal inhibitory portion of the wave at this point The result is that the inert area is driven onwards by the contracting wave tugs on the mesentery *and causes colic Should the mesentery be thin and* inelastic as in infants this point is driven into the lumen and intussusception results The colicky pains associated with *inflamed* mesenteric glands *are analogous* for we have seen how these by their inflammatory stimulus to the mesentery may inhibit an associated segment of bowel

Accordingly I have seen typical acute rheumatism associated with intussusception while lesions of this origin occurring *in* the appendix explain the frequent occurrence of appendicitis in different members of a family who living together are exposed to similar *infective conditions*

It is noticeable that intussusceptions of such origin are usually either ileal or arise in the cæcum This origin further explains recurrent intussusception *for which I have operated for the third time* in the same patient (the intussusception being of a different type on each occasion) Time does not allow me to adduce all the available evidence in support of this contention I only emphasise it as an instance of direct inhibition of the bowel wall from extra-abdominal causes and to call attention to the wisdom of examining for and remedying the source of the infection when the intussusception is cured

Finally I suggest that many instances of recurring colic of obscure origin (particularly in children) may be attributable to such small *undetected inhibited areas in the bowel wall arising from* a subacute or chronic infective focus Such for instance I believe to be the nature of the abdominal pain arising after serum administration and I have frequently seen such recurrent attacks (often attributed to chronic appendicitis) disappear permanently after attention to the teeth and throat where medicinal measures have constantly failed

Conclusion

In conclusion the aim of this critical study of over 300 intestinal cases has been to show that there is a large group of visceral disorders primarily initiated by a derangement of normal nerve impulses The main points to which I desire to call attention may be briefly epitomised It is a law of the intestine that increased work is always responded to by increased effort leading to hypertrophy This truth is exemplified clinically in the results of mechanical obstruction in every part of the gastro intestinal tract while physiologically, it has been demonstrated by the work of Bayliss and Starling No such hypertrophy is ever seen in the visceral disorders under discussion, and this fact alone constitutes an a priori refutation of any mechanical origin *as applied to the bowel itself The establishment of* attenuation and muscular relaxation of the colon, so characteristic of this group of disorders, is only possible if this physiological response to an increase of work is prevented, either by primary intramural disease, or by prolonged active inhibition of its musculature, due to abnormal direct *or* reflex nerve impulses *The role of the mesentery is to* carry vessels and nerves to and from the intestine and never to act as a supporting structure, when it so acts (e g, in congenital mobility of the colon) mechanical stimulation of the contained nerves results The truth of this is evidenced experimentally and at operations, and I *have tried to show that it is equally true pathologically*

Experimental difficulty in stimulating the vagus contrasts strikingly with the ease with which sympathetic stimuli may be evoked, and this feature is responsible for the domination of sympathetic inhibition of the bowel musculature resulting from a pathological stimulation of its dual nerve supply The domination of sympathetic inhibitory impulses is an essential feature in intestinal propulsion by *peristalsis (as opposed to the domination of parasympathetic* impulses responsible for rhythmic contractions), and this mechanism is pre eminently initiated through mechanical stimulation by the *bulk* of contents, in regions where the contents are solid or semi solid (i e, in the colon) This is *analogous to the mechanism in animals whose food is bulky* For this reason the ease with which such a dominating innervation can be excited pathologically is responsible for the fact that the colon is so often the primary origin of visceral disorders

I have tried to show that the mesentery is one of the most *important factors in the causation of disease owing to the* susceptibility of its contained nerves to pathological stimulation a fact supported by common clinical experience For in acute intestinal obstruction the profound collapse associated with mesenteric strangulation contrasts with the insidious onset of symptoms when *the* bowel alone is *involved Inflammatory stimulation is evident in the* ordinary symptoms of peritonitis, while the possibility of mechanical stimulation is demonstrated by the similar symptoms (manifested in a less striking degree) initiated by congenital abnormalities in analogous situations (i e, mesenteric bands visceroptosis &c) *I have adduced* clinical evidence in support of the view that inhibitory sympathetic stimuli can be initiated mechanically, by experimental as well as pathological traction

When, therefore, the normal supports of the colon are relatively inefficient from any cause, the mesentery assumes *the additional function of a supporting structure or ligament* The resulting efferent and afferent sympathetic stimulation are responsible for the direct and reflex inhibition of the bowel musculature which forms the starting point of intestinal stasis Thus a vicious circle is established and the condition is bound to be progressive Operations for fixation *of the colon in its normal relationship* should be designed towards a relief of the pathological tension on the nerve bearing mesentery, and the transference of such tension to regions where essential nerve impulses, both efferent and afferent, are not exposed to interference Such is the *object to be aimed at in the various methods of* colopexy, the permanent success of which is evidence in support of its value The success attending right sided colopexy has recently been demonstrated in a masterly study of a large series of operations by Mr G E Waugh The *fact that he has performed colopexy with a different* object in view does not prohibit me from accepting his gratifying results as additional evidence in support of my hypothesis

Finally, in a few advanced cases the neuro-muscular tissue of the colon is *itself damaged,* either *primarily* or *secondarily beyond the possibility of repair* When this degree of destruction is definitely ascertained no fixation operations can possibly be of value, and resection of the grossly diseased portion offers the only prospect of cure

To summarise in parable The intestine represents the horse *the mesentery the reins,* and the *central nervous* system the driver Have we not in the past concentrated too wholly on the horse? And may not a closer attention to the latter two enable us to guide the former to a more adequate performance of its functions?

Such *have been the objects of this investigation* If I have not entered into sufficient detail on many points of importance such a defect is due to the fear of rendering such a complex and extensive study too unwieldy and of obscuring the main points at issue *This conception of the pathology of many visceral disorders has been of consider*able assistance to me in its clinical application to the surgery of abdominal disease, and I hope that further study in this direction may prove of value in the future

TREATMENT OF THE CONVALESCENT SOLDIER.[1]

BY T. E. SANDALL, C.M.G., T.D., M.D., B.C. CANTAB.,

COLONEL (T.F.), LATE COMMANDING 1/5 BATTALION LINCOLNSHIRE REGIMENT, AND TEMPORARY LIEUTENANT-COLONEL, R.A.M.C., COMMANDING NO. 15 CONVALESCENT DEPÔT, B.E.F.

(*With an Appendix on Physical Training Games.*)

MANY advances in medicine, surgery, and preventive medicine, as well as many new methods of treatment, have been placed on record during the past few years as the result of experience gained during the war. As far as I am aware, however, nothing has been published on the subject of convalescence in general and of the treatment of convalescent soldiers in particular. Treatment during convalescence does not, as a rule, fall within the view of the consultant, it is regarded as uninteresting by the general practitioner, and its importance is, I think, scarcely recognised by those in the medical services whose attention has not been called to it and who have not had practical experience of the modern methods.

I do not intend to describe the gradual evolution of the method of treatment ultimately adopted as giving the best results, but I propose to give a brief description of the method in its full development, which has been of immense importance and value, not only to the convalescent soldiers themselves, but to the army in general and to the nation at large.

It is, perhaps, desirable that the writer's qualifications to speak on the subject should be explained. The methods of treatment and the results obtained are described as the outcome of personal observation and somewhat large experience. After three years' combatant service in command of a battalion in the field, I was given a temporary commission in the R.A.M.C. and entrusted with the organisation and administration of a large convalescent depôt in France from the very beginning until it ultimately attained its full complement of 5000 patients. During my period of command many thousand convalescents passed through my hands, and apart from a general supervision I had the opportunity of personally examining carefully a very large number of men and noting the results of the treatment employed.

Convalescent Treatment.

I wish first of all to emphasise the importance of convalescent treatment, which I think is often underestimated, if not neglected. Neglect of proper treatment during convalescence and wrong methods of treatment, especially in the earlier periods of the war, were responsible for an immense loss in effective numbers in the army, great waste of money and man power, and in some cases for prolonged, and even permanent, ill-health in the individual. A quick return to health is important in all cases, but in the Services it is vital that this should be procured in the shortest possible time.

The usual conception of convalescence is a period of rest and quiet enjoyment of a somewhat idle existence, with no active treatment. As a general rule convalescent soldiers at home, especially in the earlier periods of the war, were allowed to "loaf," and their stay in auxiliary hospitals was frequently unduly and unjustifiably prolonged. This was absolutely wrong; convalescent treatment to be successful must be active treatment under strict medical supervision.

The difference between the ordinary convalescent civil case and the convalescent soldier must be clearly appreciated. The object to be attained in treating the convalescent soldier is to render him fit to take his place again as a fighting man in the shortest possible time and in the most economical way. The mere comfort and enjoyment of the patient, pleasant methods of treatment, the pleasure of a lengthy stay in a charming watering-place, a congenial climate, all are useful, but must not be considered except in so far as they conduce to making the patient fit again without delay. The good of the army in general, not of the patient alone, is the supreme object, and this is attained by returning him physically, mentally, and morally fit to take his place again in the army at the earliest possible moment.

Quite apart from the disability due to his wound or sickness, the health of the convalescent soldier is impaired by the very fact of his admission to hospital. For a longer or shorter time, according to the serious nature of his disability or otherwise, he has not enjoyed the advantages of the open-air life, the hardening effect of work and exercise; he is out of training; discipline has been necessarily relaxed during his stay in hospital; he may have been better fed, but he is wanting in tone; his efficiency as a soldier is considerably impaired. He is obviously unfit immediately on discharge from hospital to take his place in his unit. He requires better food, more rest, and better conditions than are possible in his unit or depôt, freedom from exposure and strain, and a gradual hardening and training before he is fit to take his place in the field.

The "morale" of the hospital patient is always lowered, and one of the first essentials of treatment is to impress upon him that he is no longer a patient but a "soldier under training." This lesson I tried to inculcate on every patient when he entered the depôt. All my officers had instructions to lay special stress on this point in their introductory address, which was given to each batch of patients on arrival.

Organisation of the Depôt and Essential Qualifications of Medical Officers.

I do not propose to describe in detail the organisation and establishment of a convalescent depôt, which may be found in the official publications, but in order to understand the method of treatment employed it is necessary to give a general idea of the organisation. A large depôt such as I commanded was equipped for 5000 patients, and for administrative purposes the commanding officer was assisted by an adjutant and a quartermaster, who were combatant officers, as well as a small number of combatant officers attached for various duties—e.g., censorship, orderly duties, supervision of work, assistance with organised sports, and so on.

The depôt was divided into five divisions, each of 1000 men, each division commanded by a medical officer, who was responsible, not only for the health and treatment of his men, but for the discipline, organisation, and administration of his division. Each division was further divided into four companies, each of 250 men, under a company sergeant-major for purposes of administration and discipline, and each company further subdivided into hut parties under non-commissioned officers selected from among the convalescents themselves.

I desire here to say a few words as to the qualifications essential in the medical officers who may be called upon to fill posts on the staff of a convalescent depôt. In the early days unsuitable officers were sometimes appointed, and a very great debt is due from the army to Lieutenant-General Sir C. Burtchaell, Director-General of Medical Services in France, for his recognition of the fact that if convalescent depôts were to be successful they demanded the services of the very best medical officers the army could supply. Elderly or unfit men with no experience outside hospital work or civil practice are quite unsuitable. The medical officer on the staff of a convalescent depôt must be young and energetic, keen, having a deep sympathy with and understanding of men, and able to gain their confidence. Professional skill is useful, but its importance is secondary compared with tact and a knowledge of men in general and of soldiers in particular. A man who has served in the front line, preferably as a regimental medical officer, makes the best officer; in addition, he should be a sportsman in the best sense of the word, able and willing to organise and join in the games and amusements of the men under his care.

The combatant officers and the warrant officers on the staff must also be of the right type and with similar qualifications. If unfit for the front line service their disability must be such as does not unfit them for hard work, and it is of vital importance that no officer, medical or combatant, or warrant officer, should be suffering from neurasthenia or neurosis of any kind.

Method of Treatment: Physical Training.

Having thus briefly dealt with these introductory matters, I will endeavour to describe the method of treatment adopted, again emphasising the point that it is not merely the restoration to physical health which is the aim and object of treatment, but the complete physical and moral regeneration of the soldier in the shortest possible time to render him fit to take his place as a "first-class fighting man" in the field. On reception in the depôt a hot meal was provided (it is always well to give a man a good first impression of his surroundings), and the men were allotted to their divisions and companies, shown their accommodation, made acquainted with standing orders, and then given time to shake down Every man was then carefully examined by his divisional medical officer and classified This classification is most important, and is the basis of subsequent treatment Any actual medical or surgical treatment required was noted and arranged for, and, in addition, the men were graded for physical training

---

[1] A thesis for the degree of M.D. in the University of Cambridge.

Physical training is the watchword of the present method of convalescent treatment, its importance cannot be overestimated, combined with a judicious amount of amusement, moral training and discipline, with good feeding, healthy surroundings, ample rest, and freedom from exposure and strain, it reduces the period of convalescence within the shortest possible limit of time

The classification adopted in the depôt under my command was as follows B 1—i e , those fit for the full course of physical training , B 2—i e , those fit for a modified course of physical training , C—i e , those unfit for physical training, who required temporary rest It frequently happened that on examination a man presented no disability and appeared physically fit for Grade A—i e , full duty with his unit, but in view of the opinion I hold strongly that every hospital patient has necessarily suffered in "morale and discipline, as I have previously explained, no man was so classified and returned for duty Each man was temporarily classified B 1, given one week s full physical training, together with all the advantages of a stay in the depôt for that period, with a view of bringing his "morale' up to the high standard required for front line service

In some depots men classified C (i e , unfit temporarily to undergo any physical training) were rejected and returned to hospital Except in the case of men really still in need of hospital treatment, I personally think this was a mistake, as it prolonged their stay in the hospital atmosphere, which tended to sap their moral fibre, and their ultimate convalescence was thus prolonged I preferred to give them a chance My medical officers were instructed not to allow any convalescent to be graded as C for more than three days without my seeing him personally, after this he was allowed to remain graded C until a week from the date of his admission, if still considered by his medical officer unfit to undergo any graduated physical training he was reluctantly returned to hospital as unsuitable at the time for convalescent treatment

The method of physical training adopted was absolutely different from the old system of physical drill by word of command Every exercise required to bring the muscles of the various parts of the body into play was performed by means of a game, so devised as to exercise the required muscles The men were quite unconscious that they were performing systematic physical exercises, there was no drill, there was no word of command Many of the games were also devised to stimulate the mental powers by requiring quick thought and rapid decision , these games involving mental training were quite as important as those with a mere physical basis Whenever possible the spirit of competition especially combined team competition was introduced into the game, which is the most useful method of fostering and encouraging the development of the *regimental spirit*, which is of such inestimable value in the British army

This new method, gradually evolved and perfected by the Headquarters Physical Training and Bayonet Fighting Staff of the army, has wrought a revolution in physical training, physical drill is a thing of the past Training now consists of a series of training games with suitable intervals of rest The men no longer regard physical training parade as an arduous and distasteful duty, they look forward to it eagerly, take the greatest interest in the games they are invited to play they thoroughly enjoy them and the benefit to their nervous system, as well as to their general health, is immense

Instructional Staff

The instructional staff consisted of an officer and two warrant officers in charge, with 20 instructors one for each company in the depôt, who belonged to the army physical training staff For convalescent depôt work the very best and most intelligent instructors are required, who should possess similar qualifications to those already laid down as essential in the medical officers I was exceptionally fortunate in my physical training officer, Captain M Fynne, Royal Irish Fusiliers, who superintended the physical training and organised the voluntary games with unqualified success In addition to the permanent staff a large number of assistant instructors from the convalescent N C O s were trained and employed

One most important point must here be mentioned Although the physical training was conducted entirely by the physical training staff, the whole was invariably supervised by a medical officer, who was responsible that no man was unduly fatigued and that no man took part in any game or exercise which was unsuitable for him The instructors were warned to watch the men carefully, to be particular to cause men to desist if they were in the least distressed , but, on the other hand, to ensure that every man did his best In any doubtful case the medical officer was always on the ground to advise and decide

It must be clearly recognised that in almost every case the convalescent, whatever his disability, is capable of taking part in some form of physical training, otherwise he is not really convalescent, and is therefore unsuitable for treatment in a convalescent depot The man with a "leg' disability can engage in "arm ' or "trunk ' exercises presented to him in the form of games in which only the muscles of the "arm" or "trunk are involved similarly the man with an "arm ' disability can play "leg games even the "heart case is benefited by carefully thought out and graduated exercises, such exercises being camouflaged under the guise of games in every instance All are able to play and enjoy the "mental exercise games Thus the necessary physical exercise is secured, the mental processes are stimulated, and in the vast majority of cases rapid progress towards restoration of bodily and mental vigour is attained

On physical training parades also the difficult task of reinculcating discipline is considered and undertaken. On the assembly and dispersal of the parade strict discipline is maintained , on the march too and from the exercise ground strict march discipline is essential, and the benefit to the men is enormous The training was graduated, and men as they improved were encouraged step by step to take part in the more vigorous training games, until they were finally fit to undergo the full course As a rule, about 75 per cent of the patients in the depot were fit for the full course arranged by the physical training staff

Malingering Inspiring Effect of Military Music

A few words on the difficult subject of malingering are not out of place My experience in a convalescent depôt is that actual malingering was exceedingly rare in the British soldier on the other hand, exaggeration of symptoms was very common In some there was a natural desire to prolong their stay in comparatively pleasant surroundings, in others the weakening of moral fibre produced either by their stay in hospital or by real long continued strain of active service caused this exaggeration I may add that my further experience in pensions work confirms my opinion that actual malingering is very rare, whilst a tendency to exaggerate symptoms of a real disability is not uncommon Here it is advisable to mention the most important auxiliary to physical training by the new method—viz , music A really good band is of immense advantage bugles drums and fifes, and pipes are found to be of great help in promoting a good and cheerful spirit amongst the men Many of the physical exercises and games are combined with music the rural dances which are taught are most valuable exercises and are extremely popular The inspiring effect of good military music is known to all, and its beneficial effect on the convalescent soldier with lowered ' morale is wonderful

I shall not attempt to describe in detail the exercises given, the graduation and modifications adopted in different classes; these have been carefully worked out, and can only be learned by practical experience. Those men fit for the full course of physical training have a short march to the exercise ground and back to the music of the band, pipes, or drums; those unfit to march carry out modified training on the assembly ground. But no man is allowed merely to loaf; every encouragement and inducement is held out to the convalescent to take his part in the exercise considered suitable for him; the guiding principle of the new method of convalescent treatment is never lost sight of—viz., that some form of physical training is beneficial and necessary whatever may be the nature of the wound or sickness from which the patient is convalescent.

The physical training described above was carried out every morning except on Sunday, when ceremonial parade services were held. These were useful both as an aid to smartness and discipline and as an opportunity for careful inspection of the men, their clothing, and so on, quite apart from the devotional side.

Value of Organised Voluntary Games.

In the afternoon physical training was continued, but in a totally different manner from the morning parade, by means of organised voluntary games. The value of voluntary games may not be appreciated sufficiently at first sight, more particularly if their careful organisation is forgotten. It may be a surprise to many who have not had personal experience of organising games among soldiers, to learn that a great number of men do not know how to play games, but such is the fact. Even football, the most popular game, has never been really played by large numbers of men who are physically fit to play. They may have kicked a football about, they have frequently watched others, but of playing the game in its true sense they know nothing. Being taught to play a game is one of the most valuable methods of training of a soldier, for the reason that, apart from the physical exercise, it constitutes a valuable moral and mental training, a method of development of the soldierly spirit, that idea of playing for his side, of subordinating his own individual good to the good of the team, that spirit of esprit de corps, of comradeship, of loyalty, of discipline, which is a most valuable asset to the soldier in the field.

To the convalescent with shaken "morale" such training is invaluable. There are two points that must be noted—firstly, that the spirit of competition must be introduced into every game; and, secondly, that the games must be of every variety in order to include men of every grade of physical fitness. The same principle is adopted with reference to voluntary games as to physical training—viz., that every convalescent, no matter what his disability, is able to play some game, and should be encouraged to do so.

Our organised games ranged from football to croquet. The organisation of the games in order to introduce the spirit of competition is essential. Our games were organised on the basis of a monthly competition between the companies in the depôt; there was always the keenest competition for the honour of holding the monthly championship flag. In order to ensure that the largest possible number of men played in the games no man was allowed to play in more than one competition, and further, which is most important, all competitions counted alike towards the championship, thus enabling the partially disabled man, who was only able to play perhaps medicine tennis, to take as great an interest in his competition, and be able to do as much for his company, as the man who was physically fit for football. Competitions in football, hockey, lacrosse, tug-of-war, cross-country running, basket-ball, "medicine tennis" (vide infra), miniature rifle shooting, cricket, and other games were held every month, equal points were allotted to each, and the company with the best aggregate of points held the championship for the next month.

Apart from the actual competitions men were encouraged to practise as much as possible, and additional games were provided—e.g., baseball for the Canadians. Lastly, every man was encouraged to watch the other competitions in which he was not playing, to help his company by cheering on his side, and generally to foster a healthy spirit of rivalry between companies, all with the idea of developing the soldierly spirit, which we endeavoured to inculcate strongly in every man before he left the depôt.

After physical training and organised voluntary games, which developed physical fitness and "morale," the most important means of treatment was organised amusements. The value of healthy amusement and enjoyment to distract men's thoughts, to cheer their spirits, to relieve the ever-present strain of active service, is very great, and therefore every effort was made to provide amusement for the men. The work of the Y.M.C.A. and kindred societies who provided recreation huts, libraries, and so on, was most valuable and useful, and, in addition, some kind of entertainment was provided practically every evening. Concerts, dramatic performances, dances, band concerts, whist drives, were provided in turn, the performers in most cases being patients in the depôt, with occasional outside assistance, always greatly appreciated, from Miss Lena Ashwell's concert parties and other friends. Lectures on various subjects, grave and gay, were also frequently given, but were not very popular; the men preferred amusement to instruction, and for the convalescent amusement is the more valuable as an aid to complete restoration to mental and bodily health. The popularity of dancing was very noticeable.

These, then, were our methods of treatment—physical training, voluntary games, and amusements. Of actual medical treatment there was only the bare minimum. Surgical dressings, of course, were necessary in some cases; a certain number of men, especially those who were obviously anæmic, had appropriate medical treatment, but the use of drugs was discouraged, except in cases where men actually reported sick, and the numbers so reporting were surprisingly small. Each divisional medical officer had a small detention hospital hut, where a man could obtain rest and appropriate treatment for a few days, but if his illness was such as to require more than three days' hospital treatment he was returned to hospital as unsuitable for the time being for a convalescent depôt. Cases requiring extensive surgical dressings were also regarded as unsuitable and are better in hospital.

Medical Inspections.

As a matter of routine administration every man paraded at least once a week for careful examination by his medical officer; the usual practice in my depôt was for the medical officer to inspect each company under his charge every fourth day. At these routine inspections men found to be fit were so graded and marked for discharge; the classification of the remainder was revised as necessary and the progress of each man duly noted.

The average stay of each man in the depôt in normal times was three weeks or a little more. If any man at the end of six weeks was still found unfit for discharge by his medical officer, he was marked for special examination by the commanding officer. These special cases came before me and their disposal was determined upon in one of three ways: a few were returned to hospital for treatment; those who in all probability would be fit in the course of a week or two were returned to their companies for continued treatment in the depôt; those likely to be some considerable time, or permanently, unfit for front line service were marked for discharge to their base depôts for examination and re-grading by a medical board. It was found by experience that a period of six weeks was ample in the great majority of cases for a man discharged from hospital as convalescent to regain his normal mental and bodily health; men who required longer were unsuitable for continued treatment in a convalescent depôt; they were usually fit for light duty at any rate, and it was desirable for every reason that their services should be utilised on lines of communications, where every man was badly wanted, in the category assigned to them by a medical board; a lengthy stay in a convalescent depôt was a waste of time, of money, and of man-power.

Results Attained by the Treatment.

Now, as to the results attained. Of the total numbers passing through my convalescent depôt in normal times approximately 85 per cent. or more were discharged absolutely fit, Grade A, for service at the front. The percentage of wounded discharged fit was considerably higher than of sick, varying from 90 to 94 per cent.; but it must be remembered that only in exceptional cases were any but lightly wounded cases sent to convalescent depôts in France. All seriously wounded cases, sooner or later, were sent to England, and must be excluded from consideration in connexion with the results of treatment as carried out in convalescent depôts in France.

The percentage of sick discharged fit varied from 74 to 80 per cent.; about 75 per cent. was the average in normal times. The total percentage of men discharged fit varied from week to week, being mainly dependent on the proportion of sick to wounded under treatment After periods of active operations, when the proportion of wounded was high—i e , 50 to 60 per cent of the patients in the depôt—the percentage of men discharged fit was considerably higher, and the average stay in the depôt considerably shorter, than during quiet periods at the front, when the proportion of wounded was low—i e , 30 to 40 per cent This, of course, was to be expected The lightly wounded man, as a rule, has been in good health up to the time of his wound, his stay in hospital has been comparatively short, he responds more readily in every way to treatment, except in those cases where the wound causes some permanent though slight disability, his "morale" and health are quickly restored

Of the cases that did not respond well to treatment, and were discharged to their depôts for re grading by a medical board, those cases that we considered our 'failures," the great majority were cases of myalgia or chronic rheumatism in some form, neurasthenia, and those classified in army nomenclature as D A H Cases of organic heart disease are different no treatment will render them fit for front line service, and they were not retained in the depot for treatment, but sent to their base depots for re grading Chronic rheumatic cases were always difficult—they generally presented subjective symptoms only, and at the best convalescent treatment only improved them up to a certain point, bad weather or any exposure caused a relapse Prolonged convalescent treatment in such cases is waste of time Cases of neurasthenia including cases of shell shock, certainly benefited by treatment to some extent, but usually responded very slowly Definite psycho therapeutic treatment was not available, for such cases the time allowed was far too short, and as the majority were usually fit for light duty on lines of communications, and in all probability would be for a long time, if not permanently, unfit for front line service, it was quickly recognised that it was useless to retain them in the depôt with the hope of their ultimately becoming really fit

A good deal of controversy has raged over the cases classified as D A H I do not propose to discuss the subject here, but merely to record the fact that "effort syndrome" cases as a rule did extremely well, when carefully watched they responded excellently to graduated physical training, and, although in numerous cases their stay in the depot was prolonged from six weeks to eight or nine, they were generally ultimately able to be discharged fit On the other hand, those cases in which the heart symptoms dated from a definite shock, or were distinctly secondary to a nervous condition, did badly (a large proportion of cases classified in hospital as D A H are really neurasthenia cases) the majority of such cases did not respond to treatment, prolongation of their stay in the depôt was useless, and they were discharged still unfit

On the whole, in spite of some disappointments and occasional unexpected failure, I think the results of the treatment adopted are a matter for congratulation, more especially if compared with results of the old method of treatment, or rather want of real treatment, formerly prevailing To return nearly 90 per cent of cases discharged from hospital absolutely fit for front line service, sound in body and mind, in an average time of three weeks to a month from the date of their discharge from hospital is an achievement of which the staff of the convalescent depôts may justly be proud, and is a proof of the soundness of the methods employed

Food and Clothing

A few other points require mention, the most important being the question of feeding

It was recognised that good feeding was essential and the full army ration was supplied With good cooking, made as attractive and varied as the circumstances of an army in the field permitted, the full army ration is ample but something more is required Biscuit may be nourishing, but is not appetising, the British soldier desires a certain bulk of food, and it was found desirable, and indeed necessary, to supply the bread ration as bread, with only a small proportion of biscuit Biscuit, when supplied was chiefly used in the making of puddings Fresh vegetables, which are most valuable, were frequently not available as a ration, the ration was supplemented in this instance by fresh vegetables grown in the depôt garden The only other supplementary article of diet provided was extra milk, this was valuable in enabling us to provide milk puddings It was not found possible, for administrative reasons, to cater for cases requiring really special diets, such are not suitable for a convalescent depôt and are better in hospital

Clothing is important, especially in winter, and the medical officers were responsible that every man was fully and properly clothed A large stock of clothing was kept in the quarter master s stores in order to make the men's clothing up to scale when necessary

Useful Employment of Convalescents

An important feature in administration was the use made of the convalescents themselves

The permanent staff was necessarily small and it was, therefore, imperative to supplement the staff by voluntary assistants in every branch of work in the depôt Employment of this kind was very popular and there was keen competition to be placed on the employed list, as this carried the privilege of being retained for the maximum period of six weeks, even though a man might be classified as fit for discharge before the end of the period of his employment The number of men thus ' employed" was very large as in addition to the assistance required in every branch of administration orderly room, quarter master s department, physical training and so on, continuous work in improvement and construction in the depot was carried on road and path making painting, repairing buildings, gardening and such like Every employed man was given one hour s physical training every day and was released from employment before discharge and given one week's course of full physical training in order to ensure that he should have the benefit of the disciplinary and moral effect of such course before returning to his unit

Conclusions

Finally, as the result of experience, I draw the following conclusions —

1 That the detention of a patient in hospital, whatever his disability, has a deleterious effect on his health, bodily and mental, and that on discharge from hospital, although convalescent from his disability, he is always unfit to return immediately to full duty with his unit

2 That convalescent treatment is a necessary corollary of hospital treatment, especially in the case of soldiers in the field

3 That every convalescent patient, whatever his disability, will benefit by some form of graduated physical training

4 That the object to be attained is not merely a return to physical health, but a real restoration of the moral tone and complete physical fitness required of a soldier at the front

5 That the best method of treatment is the system of graduated physical training, aided by voluntary games and amusements, which tends to develop moral character and the soldierly spirit, which are as essential as physical fitness

6 That by this method nearly 90 per cent of sick and lightly wounded men can be returned to fighting units perfectly fit to take their place in the field in an average time of less than one month from the date of their discharge from hospital

7 Lastly, that the result has been of inestimable advantage to the army, an immense economy in money, an enormous saving in man power, and an undoubted benefit to the nation

APPENDIX

Physical Training Games

A brief description of some of the various games used in the treatment of convalescent soldiers is given below These games are very numerous, and a description can be given of only one game in each group corresponding to a group of formal physical exercises

Each table of exercises laid down in the training manual consists of (1) introductory exercises—i e , simple exercises arranged to stimulate the circulation and prepare the body for the more strenuous general exercises, (2) general exercises, arranged in groups to develop and strengthen the various groups of muscles in every part of the body , (3) final exercises—i e , easy exercises during which the actions of the heart and lungs, accelerated by the general exercises, regain their normal rhythm. Each day the programme of games for convalescents is arranged to begin with introductory games, followed by general games, with a view to exercising special groups of muscles, and miscellaneous games, and ending with quiet final games.

Introductory Games.

"*O'Grady Says.*"—The players are formed up in open formation as for physical training, and the instructor gives a series of commands for exercises or drill movements well known to the players. The latter do not execute any order unless it is preceded by the words, "O'Grady says." For instance, "Quick March" is ignored, but "O'Grady says Quick March" is responded to. Any player performing a movement when he should not, or vice versa, stands out, and the last man left in the class wins the game.

This is an excellent introductory game, affording mental training, as it involves quick appreciation, rapid decision, and smart action; it also causes considerable amusement.

Crows and Cranes.—Ranks are formed up at 2 paces distance and 2 paces interval, backs towards each other and looking towards their respective fronts; ranks may stand, or sit tailor fashion, or lie out of distance of one another. Two finishing lines on the ground are required 20 to 30 paces in front of each rank. One rank is called "Crows," the other "Cranes." The instructor names the rank to be chased, rolling the "r" thus, "Cr-r-r-rows," but finishing the word suddenly, whereupon the rank named will endeavour to double to the finishing line without being touched by the other rank. Those touched join the opposite rank and change their names; on the word "Ready" all return to the starting-place, though possibly the ranks have been diminished or augmented respectively.

This is also a good introductory game, involving quick thought.

General Games.

Dog Collar.—Two players face each other on hands and knees, heads in the "head backward bend" position, hands on the ground in front of the head. A rope 5 feet long with the ends joined together is placed over the back of the head of both players, and a line drawn on the ground between them. On the word "Go" each player tries by pulling to make the other advance his hand over the line, thus deciding the winner. In order to introduce the spirit of team competition the players are divided into two sides, the side having the majority of individual winners, of course, wins the game.

This game strongly exercises the muscles of the neck and upper part of the spine, as well as the arm muscles.

Under Passing Relay Race.—The players are formed into two ranks facing a flank, all excepting the last in each rank with their feet at least three foot lengths apart, bending forward from the hips, and grasping the hips or belt of the man in front, the leading player in each rank holds a soft ball, and the rear one bends down in a position to receive it. On the word "Go" the leading man throws the ball backwards between his own legs and those of the player in his rear. As soon as the rear man receives it he runs to the front of his row, and goes through the same procedure as No 1, and so on, until the original leader gets the ball, when he races to the front and places the ball on the ground between his feet; the first rank to do this is declared the winner. Should the ball go outside the players' legs, or not reach the rear player when thrown by the leader, the nearest player fetches it, if necessary, and passes it on as described.

This game is designed to exercise the muscles of the back.

See-Saw.—The players are formed up in two ranks at double arm length intervals, standing back to back in pairs with interlocked elbows. On the word "See-Saw" the front rank men bend forward, raise the rear men off the ground, then relax, and allow the latter to raise them, and so on alternately. The raised man should keep his legs together and bend them upwards from the hips; the player lifting should have his feet apart and raise slowly.

This game is designed to exercise chiefly the abdominal muscles, as well as those of the back and arms.

Side Passing.—The players are formed up in two ranks standing with feet apart, and a sand-bag or football is passed from right to left and vice versa as many times as ordered by the instructor; each player must handle the bag or ball; the rank to finish first scores one point. As a variation the ranks may be turned to a flank and the bag passed down the left side and up the right and then back again.

This game is designed to exercise the side muscles of the trunk, as well as those of the arms.

Wrestling for Pegs.—The players are divided into pairs, each pair provided with two smooth pegs, 12 to 16 inches long and 2½ to 4 inches in diameter. The men of each pair face one another and grasp the pegs left hand to right and right hand to left. On the word "Go" each tries to wrench the peg from his opponent.

This game provides strenuous exercise for the muscles of the arm and forearm, as well as the trunk muscles.

Jumping the Stick Relay Race.—The players are formed up in two ranks turned to a flank 6 paces between ranks. The first two men of each rank hold each one end of a parrying stick, and stand in such a manner that the centre of the stick is opposite the front man of their rank. On the word "Go" they run down the sides of their rank, making the men jump over the stick. The original front man of the rank, holding one end of the stick, places himself in the rank at the back, while the other one runs to the new front man with the stick, whereupon these two make the rank jump as before, and so on until the last man is reached. The latter races to the front with the stick. The first rank to finish wins.

This game, involving jumping, exercises the leg muscles principally.

Medicine Tennis.—This game is played by four players over a tennis net, but with a football, the hands being used. The point is lost by failing to catch or return the ball. The court is marked out as for Badminton.

Miscellaneous Games.

Circle Touch Ball.—The players stand in a circle 1 to 2 paces apart, facing inward, with one player inside the circle. A football is passed low from one player to another by hand, and the player inside the circle endeavours to intercept it. If successful he changes places with the last thrower. If the ball falls to the ground the player responsible either for the bad pass or the miscatch changes places with the player inside the circle.

This game, exercising the trunk and arm muscles, is an excellent game for men with "leg" disabilities.

Hand Ball.—Goals are marked (width 6 to 8 paces) on any sized ground to suit the number of players. The players (any controllable number) are arranged in two sides approximately as in football. A football is passed from player to player along the ground, the object being to knock it between the goal boundaries. It can be dribbled by hand by any player any distance backward or forward, but must not be kicked, carried, or knocked into the air. No charging, holding, or any rough play is allowed; the penalty for infringement of these rules is a free hit.

This game, which involves strenuous exercise, is one of the best games for convalescents able to perform full physical training.

Relay Races.—These races, of which there are many varieties, can be arranged for suitable distances, and are particularly useful in teaching the spirit of team competition as opposed to individual competition.

Wheelbarrow Race.—The players are formed up in two ranks extended to full-arm intervals. Two lines for starting and finishing points are marked on the ground 15 or 20 paces apart. The front rank assume the "on the hands-down" position with the feet astride and hands on the starting line. The rear rank lift the legs of their front rank men and on the word "Go" the pairs race to the other line wheelbarrow fashion, the "barrow" keeping his legs stiff, and the wheeler keeping pace with him but not pushing the "barrow." Both ranks act as wheelbarrows in turn.

This game involves strenuous exercise of the arm, shoulder, abdominal, and back muscles.

The games described above are selected from nearly 100 games, some of them with numerous variations, which are detailed in the official pamphlets issued for the use of the army gymnastic staff. Of these about 25 are introductory games, 50 general games (i.e., devised to exercise particular groups of muscles), and 25 miscellaneous games.

As final exercises after the games a few formal movements taken from the physical training tables, such as "heels raise," "knees bend," "arms raise forward and upward, lower sideways and downward," quietly performed, form the best conclusion to the day's programme.

My thanks are due to Lieutenant-Colonel R. A. Ray, D.S.O., the Commandant of the Army School of Physical Training, for his kindness in giving me the opportunity of referring to the official publications.

POST-SALVARSAN JAUNDICE.

BY RUPERT HALLAM, M.D., CH.B. EDIN.,
DERMATOLOGIST, ROYAL INFIRMARY, SHEFFIELD.

THE purpose of this paper is to draw attention to the prevalence of jaundice occurring during the treatment of syphilis with arsenobenzol preparations, and also to show that it is relatively more frequent with some preparations than with others. Jaundice occurring in untreated syphilis is a well-recognised entity, and was well known long before the salvarsan era. Lancereaux claimed that it was first discovered by Paracelsus, a noted physician, early in the sixteenth century, but the credit for definitely establishing the association between jaundice and syphilis is due to Gubler, who, in 1853, published a monograph in which he described five cases. He maintained that, as it occurred at the time of the eruption of the secondary rash, it was probably due to a similar condition developing in the mucous membrane of the bile-ducts. Jonathan Hutchinson refers to two cases which were recorded by Wilks in the Pathological Transactions for 1867. During the later stages of the disease it may be associated with cirrhosis or gummata of the liver. Icterus is, however, an infrequent occurrence in untreated syphilis at any stage. Werner, in 1897, noted it 57 times in 15,799 cases—i.e., 0·37 per cent. Scott and Pearson,[1] in a recent analysis of 2243 army cases, met with it twice. My own figures bear out the infrequency of the complication, for I have only seen one case, that of a woman, in the last 1200 patients. Post-mortem records of this condition occurring during the generalisation stage are not numerous, for deaths at this stage are uncommon. It would appear that the pathology is not always the same, for it has been by various authors ascribed to duodenal catarrh, pressure of lymph glands, affection of the blood vessels of the portal canal, catarrh of the bile ducts, and also to the direct action of the toxin of the *Spirochæta pallida* on the hepatic cells That the *Spirochæta pallida* has a predilection for the liver is a well established fact, for in deaths from congenital syphilis that organ is found to be more affected than any other abdominal organ

[1] American Journal of Syphilis, October, 1919.

Rolleston[2] states that the diffuse pericellular cirrhosis of congenital syphilis is regarded as being pathognomonic, and he is inclined to think that the most probable explanation of the jaundice in the acquired form is a catarrhal condition of the small hepatic bile ducts, which is merely part of a general syphilitic hepatitis, and that the change in the liver is probably a pericellular infiltration, with small round cells, like that seen in hereditary syphilis

The theory of the direct action of the toxin on the hepatic cells appears to find favour with most observers The jaundice is well marked, and is slow to disappear unless treated by anti syphilitic remedies

Since Klausner[3] first recorded salvarsan jaundice in 1911, there have been numerous articles in continental and American journals relating additional cases Pulvermacher[4] related 9 cases, and in a further communication in April, 1919, 16 cases, being 2 75 per cent of cases during 15 months Hermann Fabry[5] recorded 12 cases Friedmann[6] 14 cases, nearly 3 per cent Harrison found 0 6 per cent at Rochester Row Fenwick, Sweet, and Low[7] described 2 fatal cases Scott and Pearson,[8] in an admirable contribution to the literature of the subject, gave a record of 39 cases occurring at a military hospital, out of a total of 2243 cases treated From July, 1919, to the end of April, 1920, 47 cases were met with at the two Sheffield syphilis clinics, 20 of these were patients attending the Royal Infirmary, and I am indebted to Dr E F Skinner for very kindly giving me full notes of the 27 patients suffering from jaundice he saw at the Royal Hospital In March of this year, in order to ascertain the incidence of jaundice occurring after salvarsan injections, I addressed a circular letter to the medical officers in charge of 32 of the large clinics in England and Wales, asking for their information on the subject From the 13 who kindly replied I have obtained the following facts, (1) that in these clinics novarsenobillon (N A B) and neokharsivan (N K) are almost exclusively used, (2) that jaundice was rarely met with during 1919, for at 11 of these clinics no case was noted One recorded 1 case, and 5 cases were seen at a large clinic in the south of England One medical officer kindly informed me that he had had 3 cases during the first three months of this year, and another had had 2 cases in the same period I have no record of the actual number of cases treated at the clinics referred to above, but the total must exceed many times the number of cases treated at the clinics in Sheffield during the same period It would therefore seem that the number of cases in which this complication has occurred in Sheffield is exceptionally high The clinics presided over by Dr Skinner and myself are entirely independent of one another, but I think that the routine treatment of syphilis is approximately the same at both There are differences in the method of intravenous injections, to a certain extent in the choice of arsenobenzol preparation, and in mercurial medication These variations I shall refer to in detail later

Clinical Similarity of the Attacks to Ordinary Catarrhal Jaundice

Clinically, the attacks are usually very similar to the ordinary catarrhal jaundice The patients often have prodromal symptoms, such as nausea and anorexia, the icterus is well marked, the urine as in catarrhal jaundice, the fæces are usually to a certain extent pigmented, the liver is sometimes slightly enlarged, but in none of my cases was either the liver or spleen palpable There is, as a rule, little pruritus The patient usually recovers in two to six weeks Cases, however, have been recorded which have commenced as apparently a mild attack, but have become progressively worse, and terminated as acute yellow atrophy For this reason alone, although this occurrence is rare, jaundice developing either before or after treatment of syphilis is of extreme importance Even the average mild attack causes considerable discomfort to the patient and usually necessitates his absence from employment owing to the feeling of malaise and his unsightly appearance The patients do not associate the illness with the antisyphilitic treatment, and usually consult their private medical attendant It is, therefore, not improbable that the percentage suffering from this complication is higher than the figures record

The following table is an analysis of the 47 cases referred to above —

ANALYSIS OF CASES AT SHEFFIELD V D CLINICS

Cases at Royal Hospital

During—	Cases	During—	Cases
September 1919	2	February 1920	3
October	3	March	5
November	0	April	5
December	6		—
January 1920	3		27

400 cases of syphilis were treated from September 1919 to end of April 1920 The arsenobenzol preparation used in each case was novarsenobillon This preparation has been used exclusively since April 1919

7 had had a previous course No jaundice
1 had had two previous courses No jaundice
3 had W R negative through the course
24 had W R positive during the course
The stage of the disease was as follows 1 primary 22 secondary 4 tertiary

In 1 jaundice developed after	3rd injection
1	4th
2	5th
2	6th
13	7th
5	8th
1	9th
2	10th

The onset of the jaundice after the last injection was as follows —

3 developed jaundice	within 1 week
7	during 2nd
1	3rd
5	4th
7	2nd month
4	3rd

Two of the patients were husband and wife Mercury given in all cases either intramuscular or inunction All completely recovered

Cases at Royal Infirmary

July 1919	1	January 1920	1
August	2	February	0
September	1	March	3
October	1	April	0
November	3		—
December	8		20

645 cases of syphilis were treated during the period July 1919 to end of April 1920 60 per cent had kharsivan intravenously no jaundice supervening The remainder had N A B (*novarsenobillon*) *intravenously and 20 of these developed jaundice* In about 40 per cent of all intravenous injections N A B had been used since June, 1918 without a single case of jaundice until July 1919

4 had had previous course No jaundice
3 had W R negative through the course
17 had W R positive during the course
The stage of the disease was as follows 5 primary 13 secondary, 2 tertiary

In 1 jaundice developed after	2nd injection
0	3rd
2	4th
2	5th
1	6th
7	7th
2	8th
1	9th
4	10th

The onset of the jaundice after the last injection was as follows —

3 developed jaundice	within 1 week
1	during 2nd week
3	3rd
2	4th
4	2nd month
3	3rd
4	4th

Two of the patients were husband and wife Mercury given in all cases orally All completely recovered

From the above table it will be observed that jaundice may occur at any stage of the disease, and that it may occur during or after a second course of intravenous treatment, although there have been no such effects after the preceding course. It may develop after a small dose, but most of the patients have had what I think may be termed a moderate course. The free interval between the last injection and the commencement of the jaundice varies between a few days and four months, and though not given in the above table, the amount of the drug used has no relation to the free interval or to the duration of the attack. All these facts are in accordance with the experience of other observers. This complication has been attributed by some to syphilis alone, and by others, with more reason, to the combination of the syphilo-toxin and the arsenical preparation. Against the former theory is the fact that my 20 cases occurred in the group which had a certain arsenobenzol preparation, yet there was no case in the group which received a different preparation. It is also of interest to note that two non-syphilitic cases have been reported as developing jaundice after treatment by arsenobenzol, one, a lichen planus, quoted by Pulvermacher, the other mentioned by Zimmern,[9] a man suffering from malaria. Scott and Pearson[10] suggest that the liver is damaged by the treponema toxin, and is rendered more susceptible to the action of the arsenic. They divide cases into four groups as follows:—

Group A.—Occurring before treatment, due to diffuse syphilitic hepatitis.

Group B.—Occurring early after injection of 606, due to diffuse syphilitic hepatitis and superadded Herxheimer reaction.

Group C.—Occurring later during the course of treatment, probably syphilitic hepatitis, and too few spirochætes to cause a Herxheimer reaction, but the additional arsenic is too much for the liver to deal with.

Group D.—Late arsenical jaundice. They infer that the condition is much the same as in Class C, but there is probably less hepatitis.

It has also been suggested that it is entirely dependent on overdosage (Heller), and on the continent inanition due to war conditions has been held responsible.[11]

Faulty Technique a Possible Factor.

I think that an examination of the above table will show that, ingenious as these theories may be, there is certainly another factor necessary for the production of the complication; otherwise it is impossible to explain how a series of cases of jaundice should suddenly occur at two neighbouring clinics when precisely the same routine treatment had been practised, at the one for 13 months previously, and at the other for six months previously, without any such complication occurring. A reasonable hypothesis would be that it is due to faulty technique, but this I am unable to substantiate, for I am assured by Dr. Skinner that he has always used the gravity method for the injection of N.A.B., and that the detail of the preparation has always been the same. I can also assert that at the clinic which I control there has been, as far as I am aware, no variation in the preparation and administration of the N.A.B. for nearly two years. It has always been dissolved in 10 c.cm. of boiled distilled water and injected intravenously by means of a syringe.

The preparation of the solution for injection is exceedingly simple, but when a large number of patients have to be treated it is, I think, conceivable that error may unintentionally be committed. Cracks in the capsules containing the drug may be overlooked, thereby allowing oxidation. Contamination of the boiled distilled water may easily occur unless this is kept under strict supervision. Also traces of the drug may adhere to the glass apparatus after being used for previous injections and become oxidised by exposure to air. The varying duration of the free interval between the onset of the jaundice and the last injection, which, as previously mentioned, may be even as long as four months, makes it exceedingly difficult to eliminate the possibility that such errors in technique are the cause.

I am informed by Messrs. May and Baker that there has been no alteration in the manufacture of N.A.B., and that they have not received one single complaint connecting the drug with the production of jaundice. If the record supplied to me from the 13 clinics referred to above can be accepted as showing the average incidence of jaundice, it is incompatible with a recent suggestion that increased toxicity of the N.A.B. is the exciting cause. No single batch of the drug was common to all cases. Doses from nine different batches were used over the period in which the jaundice occurred. But it is significant that, as stated at the foot of the first table, no jaundice supervened after intravenous kharsivan injections. Again, referring to the 39 cases recorded by Scott and Pearson, one finds that with the exception of the fatal case in which the particular arsenical preparation used is unknown all had N.A.B. sometime during the course. Some of them, it is true, had other preparations in addition. All the cases recorded by Pulvermacher (25), Fabry (12), and Freidmann (14) had had neosalvarsan injections.

Ravaut's statistics of the French Army are as follows:—

7 cases of jaundice occurred after 37,352 injections of N.A.B.
8 „ „ „ 35,826 „ N.S.
1 case „ „ 9,215 „ S.

I think it may therefore be definitely assumed that the use of arsenobenzol preparations is conducive to the production of jaundice during the treatment of syphilis and that it is more commonly met with following the injection of the 914 (neosalvarsan) group than after the 606 group (salvarsan). It is also evident that the percentage of cases is very irregular in its distribution, and that therefore there must be at times another factor responsible. In support of this contention is the outbreak which took place at a German hospital. This was described by Franz Muller in a discussion at the Berlin dermatological meeting on March 18th, 1919; 22 cases occurred at the Ingolstadt Hospital from December, 1917, to March, 1918. Fourteen of these proved fatal and eight recovered. Neosalvarsan in total doses of 1·65 g. to 4·05 g. was administered over a period from 5 to 12 weeks. The technique and dosage were identical with that which had been used in numerous other cases from October, 1917, onwards, without any complications occurring. The mild cases began with fever and vomiting, which subsided in about eight days. The liver in most of the cases was enlarged.

The fatal cases had a similar onset, but usually with a higher degree of fever, followed by an afebrile second stage. During the second stage there were persistent vomiting, reduction in the size of the liver, abdominal pain, and, after a few days, coma and death. Post mortem the liver showed a high degree of central necrosis and fatty degeneration. He also mentions the remarkable fact that one of the medical staff, in making a post-mortem examination of the first fatal case, accidentally cut himself. Within a few days he developed acute yellow atrophy of the liver and died. His W.R. was negative, and, as far as is known, he had neither suffered from syphilis nor had he received any organic arsenic preparation.

Conclusion.

With such evidence before one it is necessary to consider whether an infection resembling Weil's disease may not be the exciting factor in the causation of the post-salvarsan jaundice which occurs in what, perhaps, may be termed epidemic form. The Sheffield cases were undoubtedly of a milder type than those at Ingolstadt, but the comparatively sudden appearance of a series of jaundice cases after many months' absolute freedom from any such complication in each clinic suggests a similarity of the cause in both towns. It is interesting to note that at both the Sheffield clinics the cases included one example of husband and wife suffering from post-salvarsan jaundice.

This grouping of cases has been described by other observers, and although there can be no definitely positive deduction in favour of an infection being responsible for the occurrence, I think the possibility is worthy of further consideration

Summary

1 That a considerable number of patients suffer from jaundice following the injection of 606

2 That it occurs relatively more frequently after the 914 group of arsenobenzol preparations (neosalvarsan, neokharsivan, novarsenobillon, &c)

3 That it may occur in epidemic form

4 That the causation is as yet undetermined

SURGERY OF CONGENITAL HYPERTROPHIC STENOSIS OF THE PYLORUS

A SERIES OF TWELVE CASES

BY RICHARD WARREN, M D OXON , F R C S ENG ,
SURGEON TO THE LONDON HOSPITAL SENIOR SURGEON TO THE EAST LONDON HOSPITAL FOR CHILDREN

THERE seems to be very great doubt as to whether medical measures can cure any cases or at any rate more than the most trifling percentage of cases, of true hypertrophic stenosis of the pylorus Thus Gray and Pirie, in THE LANCET of Sept 20th, 1919, quote 54 cases at Great Ormond street, treated for the most part medically, with a mortality of 80 per cent A collection of cases at the East London Hospital for Children gave 30 cases treated medically, which all died except one, and in this patient the diagnosis of congenital hypertrophic stenosis was finally questioned by the late Dr Eustace Smith From time to time physicians have published series much more favourable to the results of medical treatment The probable explanation is that there has been a confusion between pyloric spasm and hypertrophic stenosis of the pylorus, and the natural conclusion is that the bulk of cases which recovered under medical treatment were of the former class The diagnosis of a hypertrophic pylorus before the abdomen is opened is not altogether easy and practically turns on one point—the presence of the little hard pyloric tumour resembling in shape and size a small acorn The other signs—projectile vomiting, visible gastric peristalsis, wasting, and constipation—may be present in both conditions On many occasions the presence of the small tumour has been suspected rather than definitely felt In one only of all the cases on which I have operated for suspected hypertrophic stenosis did I find a simple pyloric spasm or ring constriction without hypertrophy In all the others there was the characteristic hypertrophy and the pyloric swelling resembling the uterus in its hardness and resilience It is difficult to conceive of this tumour disappearing under such measures as gastric lavage, further, the tumour has been known to persist for several months in a patient relieved by gastroenterostomy, who died from other causes If, then, surgical measures give reasonably good results, the obvious conclusion is that they should be undertaken as soon as the diagnosis can be made with any sort of probability, for it is the weakening under prolonged medical treatment, to which these cases have often been subjected, which renders surgical procedures so difficult and often fatal

I have records of 12 cases treated surgically, for the most part by gastro jejunostomy, with the following results —

Operation	Lived	Died
Gastro jejunostomy	6	4
Pyloroplasty	0	1
Ramstedt's operation	1	0

The average age at operation was 7 weeks the average weight 7 lb 2 oz , and the average time at which vomiting was noted to commence was 3 weeks

Comparison of Various Operations

I commenced by using gastro-jejunostomy because it is a type of operation which an abdominal surgeon is constantly employing in various forms in which he has acquired considerable facility, and which must relieve any sort of pyloric stenosis The success met with in the first case done ten years ago encouraged me to continue this method This patient when last seen a few months ago was a healthy schoolboy who seems to have suffered no inconvenience from the vicissitudes through which he passed in the early months of his life Divulsion of the pylorus (Loreta) never looked promising to me on account of the massive proportions of the hypertrophic pylorus in the cases I have encountered and uncertainty as to the amount of stretching necessary to obviate the stenosis, hence I have never performed this operation Some years ago before learning of Ramstedt's operation I attempted pyloroplasty in a case which seemed too weak for gastro jejunostomy In dividing the muscle of the pylorus a small hole was made in the mucous lining, and after mending this I fully realised what I had previously suspected, the impossibility of suturing the muscles so as to render the pylorus more patent Any suturing of the hard muscle only converts the original small circular opening into an equally impervious slit This unfortunate experience made me rather shy of dealing with the pylorus directly Ordinary posterior gastro jejunostomy seemed to be the operation of choice, the results were not ideal, but greatly superior to those obtained by medical means especially if the operation was not too long delayed Ramstedt's modification of pyloroplasty (division of the pyloric sphincter down to the mucosa without suture) seemed to present several technical advantages In the first place, the incision to bring the pylorus out is a good deal smaller than that needed for a gastro jejunostomy, moreover, it can be made higher up the abdomen so as to come over the liver, which in infants comes some distance below the costal margin This has the great value of preventing prolapse of intestines should the little patient strain Small infants are not easy to anæsthetise satisfactorily, and even with the greatest care are likely to become too lightly anæsthetised and to strain Prolapse of intestine is a most awkward complication of these operations and of those for acute intussusception and is likely to cause sufficient shock to turn the scale against the patient The small high incision of Ramstedt's operation practically obviates this danger, and the fact that no suturing of stomach and intestine is needed reduces the time of the operation by about 10 minutes The only real difficulty is to avoid injuring the mucosa at the duodenal end of the pyloric hypertrophy when dividing the muscle of the pylorus, owing to its closer attachment here to the muscle The division must be made with the greatest care, and if a hole in the mucosa be made it must be closed with a very fine suture, taking up the submucous coat only This accident happened in the one Ramstedt operation in this series and did not appear to affect the convalescence which was very similar to that in the cases treated by gastro jejunostomy

Post operative Conditions

The main thing noted was the cessation of projectile vomiting The gain in weight was variable at first, often going up steadily for a week or so and then remaining stationary for some days or dropping for a while There was seldom a steady gain for the first few weeks, but after that the gain was often exceedingly good The average gain in weight in the gastro jejunostomy cases was 5½ oz a week when observed for six to ten weeks but for the first two or three weeks the gain was often very slight in spite of varied plans of feeding The case in which Ramstedt's operation was done is a good example of this During the first two months the gain was at the rate of 3 oz a week, but in the next month at the rate of 10 oz , making an average for the three months of 5 oz a week There is evidently a considerable disorder of metabolism in these infants possibly, as suggested by Gray and Pirie a deficient activity of the pancreas and disordered suprarenal function Various diets were employed including peptonised milk, whey, modified milk, and pure citrated milk It was often necessary to experiment in order to find the most suitable diet from time to time

Conclusions

1 Most cases of congenital hypertrophic stenosis of the pylorus die if treated medically

2. Surgical measures, including cases which have become debilitated by overlong expectant treatment, have cured at least 60 per cent., whether by gastro-jejunostomy or Ramstedt's operation (Gray and Pirie).
3. Where the diagnosis is reasonably certain from the finding of a small tumour, presumably the pylorus (with the other signs of pyloric obstruction), operation should be undertaken without delay, and should be regarded as the normal treatment.
4. Where the diagnosis is not absolutely decided medical measures (gastric lavage and small feeds) may be continued for a few days while careful frequent examinations are made for the pyloric tumour. If projectile vomiting persists, fæces remain abnormal, or the weight does not increase, a laparotomy should be done high up in the abdomen and the pylorus hooked up through a small incision and examined.
5. Although there is not much difference between the percentage recovery of the cases in this series treated by gastro-jejunostomy and the Great Ormond-street series treated by Ramstedt's operation, the latter will probably be the operation of choice in the future on account of its less severe character. If employed early in all cases the results could probably be considerably improved.
6. There is a great disturbance of metabolism in these infants, rendering the after-treatment a problem in feeding to be solved in each case individually.

I must express my thanks to my house surgeon, Mr. Bettinson, for his care in collecting the notes of the Shadwell cases.

Weymouth-street, W.

FISTULA OF THE PAROTID:

AN IMPROVED METHOD OF CURE.

BY HENRY CURTIS, B.S., M.D. LOND., F.R.C.S. ENG.,
SURGEON TO THE METROPOLITAN HOSPITAL; LATE SURGEON TO THE MILITARY HOSPITAL, ENFIELD-ROAD, E., AND TO THE HOSPITAL FOR FACIAL INJURIES, BROOK-STREET, W.

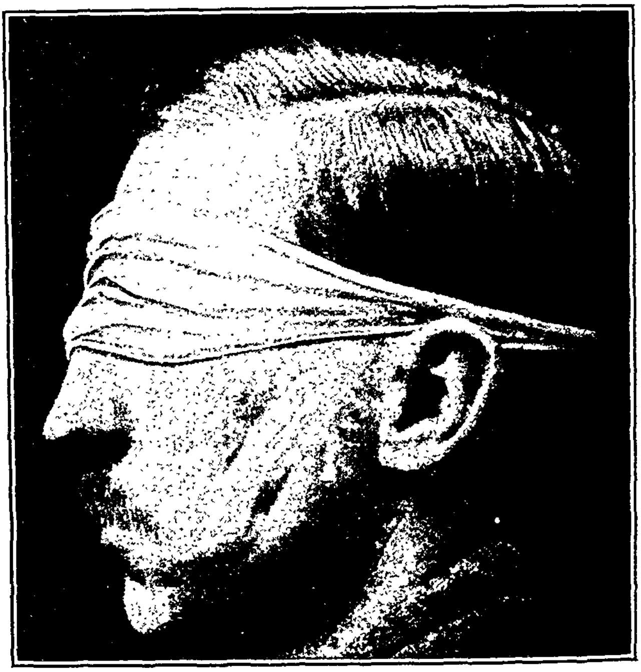
IN THE LANCET of June 7th, 1919, Mr. Percival Cole wholly condemns seton operations for the cure of complete fistula of the parotid duct, as they usually fail, he says, and render more difficult any subsequent reparative procedure. In the two cases on which he performed the operation he advocates "several previous attempts to cure had been made by seton methods, the only result being to diminish plasticity by the increase of scar tissue, and so add new difficulties to those already existing."

Starting with the principle that "if the duct will not meet the mouth cavity, the mouth cavity must be made to meet the duct," essentially the procedure recommended by Mr. Cole would appear to be based on the older operation, quoted in my article on "Affections of the Salivary Glands" in the "Index of Treatment," of freeing the portion of the duct proximal to the fistula and bringing it into the mouth through an opening at the level of the anterior border of the masseter. Mr. Cole's modification consists in leading the freed duct through the slit-up apex of a pouch of buccal mucous membrane, caused to bulge into the wound made by a generally horizontal skin incision through the cheek; the pouch when slit is sutured to the deep structures of the cheek, and the resected end of the duct then anchored to the mucous membrane within the mouth.

This operation in the two cases he records has given Mr. Cole excellent results; but, in my opinion, if cure can otherwise be effected it should not at once be resorted to. Though it is true that an ugly scar, if present, can at the same time be excised, Mr. Cole's operation itself involves a fresh cheek wound, which is not so inevitable as might be assumed. The following case, where there were two fistulæ, and one other case were treated successfully by a modification, devised by me during the war, of an old procedure which Mr. Cole, presumably, would include in the category of the condemned seton operations.

Excision of the two huge scars shown in the accompanying photograph, in the centre of each of which was a salivary fistula, would have been inadvisable, even if practicable, as the fistula treated in the anterior (upper) scar healed straight away and that in the posterior (lower) one later on, without fresh incisions.

If such a test case can be so cured, the method in its improved form may be deemed worthy of more extensive trial before resorting to Mr. Cole's open operation, suitable as it is, if the simpler method fails.



A case of two salivary fistulæ, one in each of the linear scars seen in the left cheek, cured by the method described in the text.

Technique of Operation.

The original method is as follows:—

The finest of drainage-tubes, threaded with silk at both ends, is attached to the eye of a probe, the fine point of which is insinuated into the mouth of Stenson's duct and brought out on to the cheek, leaving the tube in the duct. The silk threads are tied over the cheek; after four days they are untied, the tube is dragged some way on to the cheek, and about ¼ in. is removed from the outer end. To the outer end of what remains a fresh thread is attached, and the tube dragged back into place, thread, however, now replacing in the track the removed portion of tube. In the same way, at intervals of four days, the rest of the tube is gradually shortened, until by the time it has been completely removed leaking from the fistula has almost ceased. If there is recurrence of leaking the procedure is repeated.

By dragging the tube across from the distal into the proximal portion of the duct, thus establishing direct continuity and correct alignment of these two portions, the results can be much improved upon. It is quite easy to insert a fairly large ophthalmic probe through the fistulous opening on the cheek into the proximal portion of the duct. The opening in the duct itself naturally lies in the floor of the fistulous opening at a varying depth from the surface. In the cases recorded by Mr. Cole there was a slit in the outer wall of the duct proximal to the stenosed end, this slit being the remains of either the original wound or of the lumen of the completely divided duct, kept open by the constant flow of saliva. In other cases, as the present writer has observed, the completely divided end of the proximal portion of the duct, as the result of scarring, is directed outwards, so as to lie sometimes immediately beneath the orifice in the skin, and a probe can be at once passed obliquely inwards and backwards along the duct. This displacement, in relation with the upper end of the distal portion of the duct, must be remedied for cure of the persistent fistula, and the procedure now recommended is directed to restoring the continuity of the divided ends.

Leaving the probe in situ, or reintroducing it later, the finest drainage-tube, threaded at both ends with "black ophthalmic D" fishing-gut, is inserted into Stenson's duct from the mouth, and its outer end dragged on to the cheek in the manner already described. A non-cutting round intestinal needle is now threaded on to the suture attached to the outer end of the tube and removing the probe left in the proximal end of the duct the needle is carefully introduced into the duct for about 1 inch and its point then made to puncture the duct and emerge through the cheek dragging with it the suture The tube is thus brought across from the distal to the proximal portion of the duct and the divided ends are placed in continuity The suture is fastened by a loop around the ear and to the loop is attached the other suture fixed to the inner end of the tube and brought out of the mouth A collodion dressing repeated daily seals the fistulous opening and seems decidedly to facilitate healing

The inner or oral end of the tube is dragged down and shortened by about ¼ inch every fourth day until it has been completely cut away The suture may be allowed to remain for some days longer if leaking persists

In the photograph the minute scar at the point of exit of the suture in the case of the lower of the two fistulæ is seen, situated about midway between the angle of the jaw and the tip of the mastoid process This fistula proved to be in an unusually large duct coming from the process of the parotid which extends inward from the deep surface of the gland and projects under the mastoid process The patient was a soldier, severely wounded on the left cheek and elsewhere by shell-fire on the Vimy Ridge April 9th, 1917, who was admitted to the Enfield road Military Hospital, under my care, on April 14th, 1917 It was not until August 3rd, however, that the two fistulæ were operated on, one in the centre of the anterior, and the other in the posterior of the extensive, and almost parallel, curvilinear wounds, surrounded by much scar tissue, as is seen in the photograph Both fistulæ treated the same day by the method here advocated healed rapidly, and the anterior one remained closed The posterior one leaked from time to time, and the operation was repeated on Oct 9th 1917, rapidly and finally closing it The patient was seen some months later, in 1918, permanently cured In an earlier case a single fistula, treated by the same method, healed rapidly and permanently

---

THE ASSESSMENT OF HAND INJURIES

BY J J SCANLAN, L R C P & S EDIN , D P H

THE introduction of the Workmen s Compensation Act, 1906, called for the assessment of a large number of cases of hand injuries The war has increased the number tenfold All over the country medical men, either on military or pensions boards, are engaged in examining and assessing men with damaged and mutilated hands and it is very desirable that uniformity should be aimed at

Anatomically, the hand resembles the foot, surgically, they differ At the wrist and ankle respectively we have the well known Colles and Pott s fractures Below the ankle we have the equally well known operations of Symes Chopart, and Lisfranc In the hand we have no such well known operations and this makes the assessment of hand injuries so difficult as compared with the foot The Royal Warrant containing the schedule of fixed amounts for different injuries under the Ministry of Pensions can be bought over the counter, so that both sides know exactly where they are A Symes and a Chopart are both assessed at 50 per cent of the amount due for a total disablement and a Lisfranc at 40 per cent No such schedule exists for injuries involving the carpal and metacarpal bones

It is not only the absence of a fixed schedule for injuries of the carpal and metacarpal bones which causes trouble in assessment Difficulties arise from faulty nomenclature and the use of expressions which are not strictly anatomical One has only to peruse three or four reports dealing with the same hand injury to appreciate this I have seen scores of medical reports rendered useless by the fact that the elementary division of the skeleton of the hand into carpal, metacarpal and phalangeal bones has often not been kept in mind The anatomy of the hand might well be taught with a little more clearness in some of the medical schools and text books I have seen medical men of experience differ over which were the knuckle joints of the hand Whether the first metacarpal bone is a bone of the thumb is another point often in dispute

Civilian and Military Assessments

The assessment of hand injuries under the Workmen s Compensation Act is a very much more difficult and complicated matter than assessing in accordance with the Royal Warrant under the Ministry of Pensions This arises from two factors Under the Workmen s Compensation Act the man s occupation has to be taken into consideration, and there is no schedule of fixed amounts for definite injuries to guide one There are geographical limitations to one's knowledge, whilst one is supposed to be well acquainted with the decisions of the courts Both sides know by this time the relative values of different hand injuries and where common sense prevails needless expense over useless litigation can be easily avoided As a result of a Home Office inquiry, now being carried out in connexion with definite injuries under the Workmen s Compensation Act, it may be expected that this Act of Parliament will be improved by containing a schedule of fixed amounts on the same principle as the Ministry of Pensions

Assessing hand injuries in accordance with the Royal Warrant of the Ministry of Pensions, the schedule for definite injuries has to be strictly adhered to The right hand is assessed at 60 per cent , right thumb or four fingers at 40 per cent , two fingers 20 per cent There is a scale for minor injuries for individual fingers and parts thereof As stated above, there is no corresponding Symes, Chopart, or Lisfranc operation in dealing with the hand, so that injuries involving the carpal and metacarpal bones have to be assessed on general considerations No matter how great the mutilation of the right hand, the assessment cannot be over 60 per cent , the value of the entire hand Injury involving loss of the carpal bones nearly invariably implies loss of the corresponding metacarpal bones and phalanges We know the assessment for the loss of the whole hand and also the assessment for the fingers, so that there should not be any great difficulty in dealing with conditions existing between these two points The thumb is the most important factor and its presence or absence will seriously affect the assessment

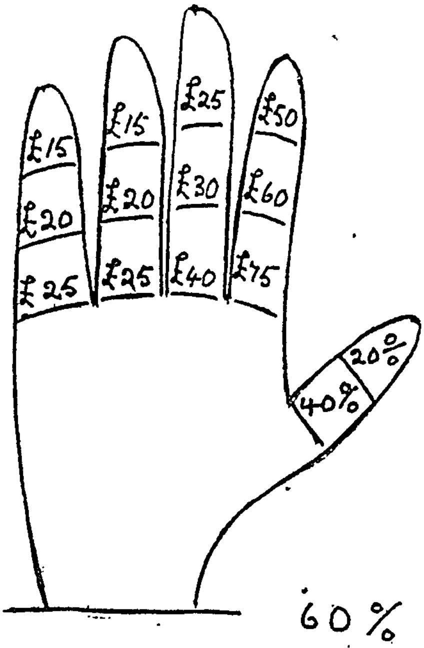
The assessments under the Ministry of Pensions must not be taken as any guide for assessing under the Workmen s Compensation Act At best they show how the Act would be improved by containing a schedule of fixed amounts for definite injuries

In assessing hand injuries it will be remembered that the function of the hand is manipulation, whilst that of the foot is locomotion Deprived of all five digits the hand is practically useless Loss of all toes interferes only in a minor degree with the utility of the foot

In reporting on hand injuries whether under the Workmen s Compensation Act or for the Ministry of Pensions the medical examiner will remember that his report will be perused and criticised and an assessment made from it by a colleague who devotes his whole time to this class of medical work To paraphrase an old saying, "An inch of diagram is worth a yard of description Failing a radiograph or photograph of the damaged hand, the simplest and most satisfactory adjunct to a medical report is an outline of the hand taken by running a pencil round the hand laid flat on a sheet of white paper For completion sake an outline of the other hand is desirable When these are supplied written description can be reduced to a minimum and common mistakes easily avoided To cite a common example a medical report states that "the third finger of the right hand has been amputated at the first joint ' To begin with you cannot be sure which finger is referred to as long as medical examiners continue describing fourth and fifth fingers The actual site of amputation cannot be determined till it has been ascertained whether the examiner means the metacarpal phalangeal joint or the first interphalangeal joint With an outline of the hand such ambiguity would be impossible

The Prognosis after Surgical Interference.

In assessing hand injuries the prospects of improvement by surgical interference will be kept in mind. The assessor will have the opportunity of utilising his surgical knowledge and of making suggestions to the parties concerned. A hand with one finger permanently ankylosed and bent into the palm may seriously interfere with the power of grip of the hand. Amputation is called for as the only means of restoring the usefulness of the hand. Refusal to undergo operation would be deemed unreasonable. Accidents arising in the employment of large corporations have the advantage that suitable work can be offered to men with certain disabilities. Our continental neighbours, owing to being State owners on a large scale, are in this position, instead of having to rely on the generosity of private concerns for the employment of disabled men. This is specially true when dealing with army pensioners. When an injured hand has soundly healed the question of change of occupation has often to be considered, and there are a variety of occupations open to men who are more or less one-handed. Considering the frequency of hand accidents amongst the industrial population the faculty of being ambidexterous should be acquired in early life.



Assessments for injuries in accordance with the scale of the Ministry of Pensions. Right hand, 60 per cent.; right thumb, 40 per cent.; four fingers (right hand), 40 per cent.; two fingers, 20 per cent. Ankylosed fingers same scale as for loss of fingers or parts thereof.

The assessment of hand injuries might almost be said to commence in the operation theatre. I remember a case in a casualty clearing station in France as an example. A man was brought in with a gunshot wound of the right hand. The proximal phalanx of the thumb was shattered, the distal phalanx undamaged. The thumb was hanging loosely on to the hand. Instead of amputation of the whole thumb, I advised clearing away the debris of the shattered first phalanx, "dropping down" the second phalanx and suturing its tissues to those at the metacarpo-phalangeal joint. This the operating surgeon did very neatly, and the man was sent down the line with a one-phalanx thumb, nail intact.

A diagram of the right hand, with appropriate assessments in accordance with the Ministry of Pensions, is appended to illustrate the facility with which assessments can be made when working to a fixed schedule, and it is to be hoped that the Workmen's Compensation Act will be improved on similar lines.

THE late Mr. David Evans, of Swansea, bequeathed £2000 to the Swansea General and Eye Hospital for the endowment of two "David Evans" beds.

THE ENTEROCOCCUS AS A FACTOR IN CERTAIN TYPES OF DYSENTERY.

BY S. M. ROSS, M.D. EDIN., D.P.H.,
BACTERIOLOGIST, DERBYSHIRE COUNTY COUNCIL;
AND
C. F. PECKHAM,
ASSISTANT BACTERIOLOGIST, DERBYSHIRE COUNTY COUNCIL.

THAT the enterococcus is very frequently the cause of a severe type of dysentery is not always recognised in this country, where this micro-organism has not been studied as abroad; in fact, in several of the most popular English bacteriological text-books it is not even described.

The organism was first described by Thiercelin, has also been described by Escherich, Tavel, Éguet, and Besson as an encapsulated streptococcus, and may be considered either as a saprophytic micro-organism which under certain conditions may become pathogenic or, as suggested by d'Este Emery, a pneumococcus which has largely lost its parasitic properties and become very pleomorphic.

If a microscopical examination only is made the organism is often called either a pneumococcus or a streptococcus, according to the form it has assumed, from the fact that it so closely resembles the pneumococcus and also occurs in streptococcus-like chains. It is, both in morbid material and in pure culture, strongly Gram-positive, and most frequently occurs as a diplococcus, of which the elements may be both lanceolate and of equal size, or unequal and one element rounded; a capsule is occasionally found.

In France it is regarded as a very common cause of enteritis in children and adults, as well as of infection of the liver; it is also stated to be the cause of some cases of broncho-pneumonia and of meningitis. The micro-organism is widely distributed, occurring in the alimentary canal, vagina, &c. Schmitz (1913) in bacteriological examinations of 3500 specimens in Germany found it only 15 times, and never in the sputum or stools in health.

The enterococcus is easily cultivated, growing at 20° C., though its optimum temperature is 37° C. Cultures on agar give small round isolated colonies, resembling at first those of the pneumococcus, though later becoming more opaque. On lactose-litmus agar it produces acid and the colonies are minute, resembling those of the streptococcus. At the end of seven days' incubation the colonies are still discrete, slightly larger, and more opaque. The growth on gelatin resembles that of the streptococcus, and the medium is not liquefied. In peptone broth there is general turbidity with deposit and clearing of the supernatant fluid after 24 hours, and it may or may not coagulate milk in which it does not grow well. In lactose, maltose, mannite, and glycerine it produces acid without gas, and it does not produce indol.

The organism is a facultative anaerobe, very virulent to mice, less so to rabbits. The enterococcus is very tenacious of life; according to Thiercelin it remains alive after four years.

An Interesting Outbreak.

An outbreak of a very severe type of dysentery, with a mortality of 42 per cent., occurred in the Chapel-en-le-Frith Workhouse in 1919. Dr. Francis G. Bennett, the medical officer to that institution, has kindly given me very full notes of the outbreak, and the available evidence showed enterococcus infection. Dr. Bennett ascribes the cause of the outbreak to the opening up of the floor of a ward, because the patients had been previously resident in the institution for years, had no suspicious article of diet, and had not, as far as can be known, been infected from outside agencies. No further cases have occurred since the cavity has been disinfected and filled up.

Considering the longevity of this micro-organism, this view of the cause of the outbreak is quite probable, but the debris was not sent for examination. The floor of the ward was disturbed at the end of the first week in March, and the first case of acute diarrhœa occurred on March 22nd, cases continuing to occur until April 7th, 1919. Dr. Bennett thus describes the outbreak.

The general symptoms were severe abdominal pains, acute diarrhœa, backache, headache, vomiting in the acute stage, in some cases sore-throat. The motions were foul smelling, containing blood and mucus in the fatal cases. The number of cases was 12; of these 5 died in 3, 6, 8, 8, and 9 days respectively.

Fæces from three of the fatal cases were sent to this laboratory. In all pus and blood were present, and the fæces were semi-liquid with a very foul smell. Direct microscopical examination of films from the fæces showed in each case a large number of Gram positive diplococci closely resembling the pneumococci, and short chains of oval diplococci were also present Plate culture on bile salt agar showed in 24 hours coliform colonies, no other colonies developed in three days but the organism has been found to grow on this medium On lactose litmus agar in 24 hours there were a large number of minute transparent colonies becoming in 48 hours gradually more opaque and about double the original size Further incubation did not seem to increase the size of the colonies which always remained discrete

The cultural reactions were as follows —

Peptone broth 24 hours growth with deposit
Agar 24 hours, minute transparent colonies
Gelatin growth not liquefied
Lactose acid
Maltose acid
Mannite acid
Glycerine acid
Milk clotted in 14 days
Peptone water 48 hours no indol

Blood from a female patient who subsequently died was procured, and at once agglutinated the enterococcus in dilutions of 1 in 30 to 1 in 120 Owing to pressure of work and shortage of staff at the workhouse hospital no further specimens of fæces were sent for examination

Two Isolated Cases

Two isolated cases, due to this organism, in which the clinical symptoms very closely resembled typhoid fever, may also be quoted, one case having been successfully treated by an autogenous vaccine

The first case was that of a young woman where the provisional diagnosis lay between typhoid fever (clinical symptoms, persistent raised temperature of 103-104° F marked general exhaustion, with abdominal tenderness and diarrhœa) and septicæmia A negative Widal reaction against typhoid and paratyphoid bacilli was obtained (patient had been ill for about three weeks) Cultural examination of the fæces gave a very abundant growth of the enterococcus and no bacilli of the typhoid dysentery group were found Vaccine treatment was refused and the patient was seriously ill for many weeks with a protracted convalescence

The other case which I am permitted to quote by the kindness of Dr Winstan St A St John, of Derby, was that of a married woman a trained nurse who during the war had been actively engaged in nursing and then went on a tour in France and Germany in 1919 While in France she became ill and though partially protected by inoculation in 1916 against typhoid and paratyphoid bacilli A and B the provisional diagnosis of her illness lay between colitis and typhoid fever The clinical symptoms were those of persistent raised temperature diarrhœa, and abdominal pain and tenderness with much exhaustion Patient had been ill for 25 days when her blood was sent for examination The Widal reaction showed slight agglutination in dilutions of 1 in 30 and 1 in 60, probably due to the previous protective inoculation but was completely negative in higher dilution and also completely negative as regards paratyphosus bacilli A and B

Bacteriological examination of the fæces gave a practically pure culture of the enterococcus and no bacilli of the typhoid dysentery group were found An autogenous vaccine was prepared from the enterococcus and administered in doses gradually increasing from 50 000 000 cocci every fifth day for five weeks by Dr St John Patient had a slight reaction to the vaccine after the first and second injection but none thereafter, and made a good recovery, prolonged somewhat by the fact that she had suffered from enteroptosis for years This patient had seven months afterwards symptoms of appendicitis, and the appendix was removed Emulsions made from the appendicular contents and plated on lactose litmus agar gave no growth of the enterococcus

Conclusion

These notes on cases which have cropped up during six months' routine work suggest the advisability of a definite search for the enterococcus in all conditions with obscure clinical symptoms somewhat resembling typhoid fever

---

DEATH OF SURGEON MAJOR R R SCOTT —Ralph Robert Scott, M R C P Irel , L R C S Irel Surgeon Major Army Medical Service (ret), has died at his residence in Bath in his eighty ninth year The deceased officer was assistant surgeon to the 16th Regiment and on the staff during the Crimean War In the Indian Mutiny he was attached to the 8th Hussars and was on the staff in Sir James Hope Grant s flying column being present at the relief of Lucknow After the Mutiny he served in India and the West Indies Surgeon Major Scott had resided in Bath for the past 25 years and was highly respected One of his sons lost his life on the *Lusitania*

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

◆

TWO CASES OF INTESTINAL OBSTRUCTION

BY W E TANNER, M S LOND , F R C S ENG ,
SURGICAL REGISTRAR TUTOR AND DEMONSTRATOR OF ANATOMY GUY S HOSPITAL

Two unusual cases, (1) obstruction of the small intestine by a large hair ball, and (2) strangulation of the small intestine by the appendix acting as a band, are here recorded

CASE 1 *Obstruction of the small intestine by a large hair ball* —E W a girl aged 7 was admitted to Guy s Hospital on March 12th 1920 She had been healthy until a year before admission when she had an attack of abdominal pain and sickness at first suspected to be due to appendicitis but diagnosed later as gastritis She recovered from this and was well until March 9th 1920 when she had an attack of acute abdominal pain with vomiting of green fluid The bowels opened twice on March 9th and on March 11th an enema was given with a small constipated result The vomiting continued until the evening of March 11th The abdomen was distended and paroxysms of pain were accompanied by peristalsis of distended bowel On admission pulse 130 temperature 97° F the abdomen was distended around the umbilicus not in the flanks with visible peristalsis of the small intestine On rectal examination the house surgeon Mr V F Lloyd felt a hard movable lump in the right iliac fossa Intestinal obstruction was diagnosed the cause being obscure

Operation —A right paramedian laparotomy was performed On opening the peritoneum clear fluid escaped the appendix was normal The small intestine was distended the cæcum collapsed and a hard movable mass was felt in the lumen of the ileum 4 inches from the ileo cæcal valve. The mass could not be broken up so it was milked through the ileo-cæcal valve and removed through an incision in the anterior wall of the cæcum because it was thought to be too large to pass the narrow part of the pelvic colon The cæcum and parietal wound were closed The mass was found to be a spherical hair ball 2 inches in diameter composed of the child s own hair matted together by intestinal fluid and a small amount of fæcal matter The mother said that the child had habitually bitten her hair since the age of 2 Neither the mother nor the child had observed if hair had been passed per anum before the onset of intestinal obstruction or after the attack of gastritis a year before The child was discharged in good health three weeks after the operation

In the literature[1] there are many records of hair balls in the stomach, but I have found no example of a hair ball causing obstruction in the small intestine

CASE 2 *Strangulation of the small intestine by the appendix acting as a band* —Henry J , age 64 was admitted to Guy s Hospital on April 13th 1920 He had suffered from asthma for 35 years When screwing a bolt on to some couplings on April 10th he was seized with acute abdominal pain He went to bed but the pain persisted The bowels had not acted since but there was no vomiting

On admission temperature 97° F pulse 80 A tumour was felt just below and to the right of the umbilicus There was tenderness and rigidity over the tumour but elsewhere the abdomen was supple Appendicular abscess was diagnosed and a right paramedian laparotomy was performed The great omentum was lifted from the surface of the tumour pus escaped and the lower 6 inches of the ileum were found to be gangrenous The appendix passed upwards and to the left and was attached by its tip to the front of the mesentery The gangrenous intestine was lying between the appendix and the front of the mesentery so that the former acted as a band strangulating the lower 6 inches of the ileum A lateral anastomosis was made between the transverse colon and a loop of ileum just proximal to the gangrenous portion and the great omentum was sutured over the anastomosis The appendix was then removed and gangrenous ileum resected the open ends of bowel being closed by double purse-string sutures The bowels acted on the second day after operation There was slight superficial suppuration of the wound at the end of four days but this subsided and the patient was discharged on May 10th

I am indebted to Mr R P Rowlands, surgeon to Guy's Hospital, for permission to publish these cases

---

HAIR BALL IN THE ILEUM CAUSING OBSTRUCTION.

BY HAROLD R GIBSON, M D , CH B ,
RESIDENT MEDICAL OFFICER LONDON TEMPERANCE HOSPITAL

So far as I am aware this is the youngest case recorded in the English literature of a hair ball in the ileum causing obstruction

A boy aged 6 years was admitted to the London Temperance Hospital on Jan 24th with a history of vomiting for two days previous to which he had been quite well The bowels had not moved the previous day, but a few hours before admission he had passed a small constipated motion.

---

[1] Wien klin Woch, Nov 16th 1899 Index Medicus since 1903

On admission he complained of slight pain in the umbilical region, but there was no tenderness or rigidity, and the abdomen moved freely with respiration. On palpation a tumour, which was slightly movable from side to side, could be felt in the right iliac fossa. The temperature was 98° F. and the pulse 94. An enema gave a very slight result. The child slept quietly all night. The following morning another enema was given and some small hard fæces were passed, but there was no blood or mucus. The abdomen was slightly distended, and coils of intestine were visible in the epigastric region.

Operation.—An operation was performed by Mr. James McClure. The abdomen was opened by a right paramesial incision. A tumour was found lying over the appendix, and at first sight appeared to be an enteric intussusception, but was found to be a mass in the ileum. It was movable in the intestine upwards but not downwards. It was moved up to a healthy part and the intestine opened by a longitudinal incision and the mass removed. The wound in the intestine was sutured and the abdomen closed.

The mass was 2 in. long, 1⅓ in. deep, and ¾ in. across, and consisted of hair tightly packed and arranged in concentric layers. In the centre it contained granular white matter resembling sebaceous material. The child made an uninterrupted recovery.

The patient, though a boy, had long hair, and on questioning the mother it was found that he had been in the habit of putting his hair into his mouth and eating it.

A SUCCESSFUL CASE OF

LATERAL INTESTINAL ANASTOMOSIS

THROUGH THE VAGINA.

By J. G. WATKINS, M.R.C.S., L.R.C.P. LOND.

ANASTOMOSIS in the vagina, though not desirable as a set operation, or if instruments for a laparotomy are within reach, may be a useful procedure in an emergency similar to the one here recorded. It may be comforting to know that a tragedy can be averted by its use, with the help of suture materials that are to hand in the meanest cottage.

The patient, a 2-para, youngest child 7, aged 44, was four months pregnant. The urine was laden wiih albumin, and as in her previous pregnancies she had had severe albuminuria, and two years ago had undergone a ventrofixation, it was decided to empty the uterus. On Feb. 24th, 1920, under an anæsthetic, the cervix was dilated to 22 Hegar. The dilatation was very easily accomplished, but little force being needed. I then punctured the membranes, and proceeded to extract the fœtus piecemeal with ring forceps. Everything appeared to be normal, except that on three occasions I brought out pieces of fat about the diameter of a sixpence.

Having cleared out the placenta and the whole fœtus, except the head, I drew down a tough, flat, shiny substance, which I took to be part of the neck, and I drew hard on it to extract the head. It appeared to stretch considerably, but for some time I suspected no abnormality, and not getting a very firm purchase I put a spare vulsellum through it. I then discovered that the flat band was a coil of empty intestine, without a mesentery, which must have been partly torn off when I observed the bits of fat and partly dragged from its attachment. I then for the first time explored the cavity with my finger and found a rent about 1½ or 2 inches long, running up from the internal os on the left side. The head was still in the uterus, but after an attempt to get a firm hold of it, it disappeared.

The patient's pulse now failed considerably, and it was thought impracticable either to remove her to a hospital or to wait until instruments for a laparotomy could be collected and sterilised, so some cotton and a sewing-needle were boiled and I made a lateral anastomosis after excising six inches of bowel and turning in the ends. After swilling it liberally with hot water I returned it through the rent into the abdominal cavity. No further search was made for the head, but a couple of strips of boiled lint were passed up through the laceration, and the patient was returned to bed and placed in the Fowler position. Later in the evening 1 c.cm. of pituitrin was given intramuscularly.

The patient's condition during the first week was very satisfactory; temperature not higher than 101·2° F., pulse 105 to 130. A very slight natural action of the bowels took place on the fourth day. On the fifth day she was given calomel gr. iii. in divided doses with no result, and on the eighth day ol. ricini ℥i., after which she had a rigor, with much abdominal pain, but the bowels were freely opened. The following day the temperature was 102·6°, but came down to a general level of 100·6° for the week, with frequent loose actions of the bowels. On the twelfth day she had slight phlebitis and thrombosis in the right leg, which soon cleared off. The third week began with the discharge from the vagina of two pieces of foul-smelling slough, each about 3 in. by 1 in., and griping abdominal pains. At this time, too, fæces began to pass through the vagina, and on the seventeenth day, as there was pain in the rectum, I examined it and drew out two fœtal frontal bones, the remaining cranial bones following during the next two days. After the end of this week no fæces passed p.v., and during the fourth week the patient suffered with constipation, accompanied by pain and dilatation, all relieved by a turpentine enema.

Since then her general condition has steadily improved, and now, at the end of two months, she is getting about, and the bowels act about thrice daily with liquid paraffin alone.

Remarks.

The case seems to me to be worth reporting, as it taught me some valuable lessons: Firstly, to be on guard in future when the cervix dilates with exceptional ease. Next, instead of scrupulously keeping the gloved finger out of the uterus to sweep it round above the internal os, to make sure that there is no laceration. Thirdly, to beware of anything in the uterus which is not obviously fœtal or placental. The intestine, as it came down, was not in the least like gut, but the bits of fat should have given me warning.

Bootle.

A CASE OF

RIGHT MASTOID SUPPURATION CAUSING LEFT-SIDED FACIAL PARALYSIS.

By E. WATSON-WILLIAMS, *M.C.*, M.B., B.C. CANTAB.,
OTO-LARYNGOLOGIST, SOUTHMEAD INFIRMARY, BRISTOL.

THE following case of a left facial paralysis produced by a right mastoid abscess is somewhat unusual.

A girl, aged 21, was admitted to the Bristol Royal Infirmary 25/10/19 complaining of pain in the right ear. The history was that both ears had discharged since infancy, but without pain or other symptoms. Seven days before admission there was intense pain in the right ear. The discharge was unchanged. Foments were applied and the pain became less on the fourth day. On the sixth day she was fairly well; that night she had two rigors, with *left* facial paralysis.

On examination the girl was found to be very ill, drowsy, and flushed. T. 100·2° F., P. 112, R. 32. She ached all over, but especially at the back of the head; there was well-marked head retraction. There was peripheral facial paralysis and external rectus paralysis on the left side; ptosis and some photophobia on the right. Pupils equal and active; fundus could not be seen. The right mastoid showed no tenderness or œdema, but there was slight redness behind the ear. The right sterno-mastoid was tender along the upper part of its anterior border. Air-conduction diminished both sides, bone-conduction appeared normal, but could not be absolutely determined in the mental condition of the patient. No vertigo. Lumbar puncture gave very turbid cerebro-spinal fluid under slightly raised pressure.

The point now was to decide which side was most to blame for the condition. The unimpaired bone-conduction on the left was taken as evidence that the facial was probably not involved at the internal meatus. But suppuration might nevertheless have determined compression in the canals. On the right side, however, there was very little pointing to mastoid involvement. The ptosis and tenderness of the sterno-mastoid were not of much help, and the patient allowed free percussion of the mastoid process. In view of her general condition and the meningitis action was imperative. It was determined to deal with the right side.

Operation.—A radical mastoid operation was immediately performed. The lateral sinus and internal jugular were thrombosed. The latter was tied at the level of the cricoid and all clot curetted out of both. The dura was exposed over the antrum, the cavity curetted clean, and the wound drained. The patient became very faint and the operation had to be completed rapidly. She rallied well; next day she was very much better and mentally clearer. The facial paralysis and ptosis were less marked. On the third day the temperature was just above normal, the facial paralysis and ptosis were practically gone; the left external rectus remained paralysed. Becoming restless at midday, she was delirious in the evening, sat up in bed, and fell back dead.

Post-mortem.—The right lung was extensively infarcted, suggesting a soft pulmonary embolism as the immediate cause of death. In the skull the thrombosis had recurred in the lateral sinus, going 1 inch down the occipital. There was an extradural abscess over the petrous on the right side, which had been drained at the operation. The dura over it was thick, soft, and red. An extensive fibrino-purulent mass reached from the curve of the sigmoid sinus across the mid-line and into the left posterior fossa, completely surrounding the third, fourth, and sixth nerves on both sides and the fifth, seventh, and eighth on the left only. The bone on the left showed no evidence of infection after stripping the dura.

The left facial paralysis and its curious diminution after operation on the right side were thus explained.

I am indebted to Dr. P. Watson-Williams for permission to publish these notes.

INSURANCE PATIENTS IN THE WEST OF ENGLAND.—The number of insured persons in Bristol is 155,825, and last year 409,495 prescriptions were dispensed. During 1919 the prescriptions dispensed for members of the Devon Insurance panel were 253,256, the cost being £285, compared with 214,957 in 1918, the expenditure in respect of which was £213. The Gloucestershire Insurance Committee report that in 1919 the prescriptions dispensed amounted to 123,000, against 134,100 in 1918.

Reviews and Notices of Books.

PROBLEMS OF POPULATION AND PARENTHOOD.

Being the Second Report of and the chief evidence taken by the National Birth rate Commission, 1918-1920. London: Chapman and Hall. 1920. Pp. clxvi + 423. 25s.

THE decline in the birth rate is one of those tiresome questions that accumulate as heavy clouds on our horizon, raising visions of disaster, which it is the troublesome privilege of the medical profession to see and help to avert. The National Birth rate Commission was privately constituted in 1908, at the instance of the late Bishop Boyd Carpenter and the National Council of Public Morals, with the support of the Government, who allowed the Principal Medical Officer of the Local Government Board and the Superintendent of Statistics under the Registrar General to serve on the Commission and contribute the official information found necessary. The first report[1] was presented to Mr. Walter Long, as President of the Local Government Board, in 1916. It was reviewed in a leading article in THE LANCET on June 24th, and was widely commented on both in the American and British press as the most candid, the most outspoken, and the most important statement on the subject yet issued. It showed that the birth rate in England and Wales had declined by about one third in 35 years; that this decline was mainly due to voluntary restriction by artificial methods, and was most marked in the more prosperous classes; and that the great incidence of infant mortality in the less prosperous classes did not counterbalance their greater fertility.

The Commission was reconstituted in 1918 and has now issued a second report on further inquiries suggested by Mr. Long. The fresh terms of reference included specifically the progress of the legitimate birth rate, the causes and prevention of the illegitimate birth rate, the influence of fœtal disease, of venereal disease, of housing and economic factors, of the industrial employment of women, the distribution of population and sexes throughout the Empire, the qualitative aspects of the birth rate, the uses of the Census and of the coming Ministry of Health in racial reconstruction after the war. Of 41 members, 12 were women, 14 were medical (including one woman and six past or present medical officers of health), 10 ministers of religion, and several well known men and women in social work and public affairs. Except for one member who died and nine who were precluded by their official position or absence from signing, this is an unanimous report, with certain important reservations on the moral issues involved. 423 pages are occupied by the evidence of the 46 witnesses, all in their several lines of outstanding importance. The book is more a symposium than an official report, easy to read, of fascinating interest, and showing a marked advance in the practical proposals discussed and to some extent recommended.

The birth rate continues to decline. Having declined by one third in the previous 40 years to 23·8 per 1000 of the population in 1912, the birth rate for England and Wales fell during the war to 17·7 in 1918, while the proportion of illegitimate to all births rose from 4·3 to 6·3 per 1000. The corresponding figures for 1918 for Scotland were 20·2 and 7·9, for Ireland 19·9 and 3·1. The birth loss due to the war over and above the decline which might have been expected from the downward curves of pre war rates is estimated at 543,087 for England and Wales, and from 650,000 to 700,000 for the United Kingdom. Against this may be set a decline in infant mortality from 105 per 1000 births in 1914 to 97 in 1918. The fall has been less in the Dominions—to 25·3 in Australia in 1918, 25·7 in New Zealand, and 29·0 in South African whites in 1917, while in the unoccupied departments of France it fell from 18·0 in 1914 to 10·4 in 1918. (The loss of births to the German Empire from all causes during the war has been reckoned at 3½ millions.) The differential quality of this decline is also now a certainty, the decline showing itself especially in the more successful families, as well in those who have risen from the ranks during the past century as in those whose position is of long standing. The Commission asks that the facts required for further enlightenment as to the parallel course of these processes in the Dominions, and as to food supply and other kindred matters, should be obtained in future simultaneous censuses throughout the Empire, while other relevant facts might be obtained by an anthropometric department in the Ministry of Health.

The national and international dangers are no longer really in dispute. Race suicide has begun. Mr. Harold Cox and Mr. J. M. Robertson may see value in a declining population, but this view requires a good deal of philosophy for its quiet acceptance. Sir Henry Rew, as Director of the Food Ministry, shows that this country before the war produced only half its food supply, and that even if production were increased to a maximum it could not completely support even the present population. We must look overseas for some at least of our food to be bought by our manufactures; and overseas there is room for boundless population. With the losses and lessons of the war ringing in our ears, the responsibility of the vast imperial estates, held by a mere 15 millions of white people apart from the 45 in these islands, demands the highest possible birth rate consistent with quality; and from the experience of the Oversea Settlement Committee and of the Salvation Army the report gives useful suggestion for the furtherance of migration within the Empire. The need for more equal sex distribution also goes to the root of morals, and an appeal is made on these grounds to the female electorate. The strength of a community obviously depends on the quality as well as on the numbers of its people, but even bare numbers contribute also to its quality. For the quality, even the happiness of its life and the efficiency of its work depend on genius and leadership in research, in æsthetics, in thought, and in action; and the larger the field of selection the better.

The Commission, therefore, makes straight for the main proximate cause of the decline in births—the deliberate restriction of child bearing—which now operates dysgenically throughout the Western world. The restriction of families as a habit began with the educated and professional classes and is rapidly spreading throughout the community. But the poorest, most thoughtless, and least responsible strata will be little affected by this tendency, while countless agencies will continue to preserve their offspring.

A valuable chapter on the ethics of voluntary restriction results in certain agreements on principle. A definite pregnancy at least should not be terminated, except under medical advice and action. Persons likely to transmit serious physical or mental taint should not have children. No married person should refuse parenthood on selfish grounds. No preventive means should be used that may injure the health of parents or child. Society should remove from parents those disabilities for which they are not to blame. The young especially should be soundly instructed in matters concerning marriage and parenthood. The attitude adopted by the several religious bodies is defined, and the arguments for and against the use of contraceptives are set out, the views given being in correspondence with different types of mind. A world that has accepted the use of chloroform to lighten the pains of childbirth will not find any sure footing on the different ledges occupied by the several opponents of "unnatural" contraceptive methods. But a line must be drawn somewhere; and in view of the precipice at our very feet, there are many reasons of expediency, both moral and material, in definitely banning all such methods, at least as an ideal, and proclaiming sexual self control in marriage, as before it, to be the highest virtue. We should the more be inclined to favour this view, looking on contraceptive methods like the use of dangerous drugs, could exemptions be allowed for adequate reasons by those competent to judge. But the report fails to consider how far this practice actually holds good in the present day, with the consulting-room as the unofficial tribunal. And a better judge than the family doctor, when guided by the general moral principle required, can hardly be devised. The medical student is passed into the outer world with only haphazard guidance as to the advice he should give on these questions of vital importance, both to individuals and to Church and State, but there are no recognised tenets in which to instruct him.

---

[1] The Declining Birth rate: its Causes and Effects. Chapman and Hall. 10s. 6d. net.

On the economic and social questions involved little is added to the first report. But it is stated that "recent legislation has effectually destroyed the child of the poor as an economic asset"; and the experience of the employment of women under the Ministry of Munitions, leading to graduation of work during pregnancy, is of practical value. The arguments for and against the endowment of motherhood are set out and left for further inquiry, with suggestions for the special consideration of cases analogous in civil life to the wives and widows of sailors and soldiers who have received help in motherhood during the war. The case of the unmarried mother is discussed in detail. Figures are given showing that the rate of illegitimate births to unmarried and widowed mothers between 15 and 45 sank from 14·4 in the years 1875–80, to 9·2 in 1896–1900, and 7·0 in 1916; but rose to 7·4 and 8·2 in the two following years. The Commission relates the causes—the war, the marriage-law, economic factors and environment; and it finds that parents are greatly to blame. But it devotes chief attention to the causes and remedies of results, especially in the reduction of maternal and infant mortality. The largest proportion of illegitimate children are the result of temporary unmarried unions: (*a*) "from sheer casualness"; (*b*) from principle; (*c*) from one or other partner being already married; (*d*) from reasons which result in subsequent marriage. It is among the class of illegitimates, whose fathers take no responsibility for them, that we find the undue rate of illegitimate mortality and it is far worse in this class than has been realised. Finally come the children of feeble-minded girls and border-line cases. The ante-natal and infantile deaths per thousand births in 1917 are given as 246 in wedlock and 507 out of it. The necessity for action is clear. The law, in its defence of marriage and of national existence, has hitherto treated the unmarried mother as an outcast, has penalised the bastard through the mother and allowed the father to escape almost scot-free. The changes suggested are those in the Bastardy Bill, which has now passed its second reading in the House of Commons, with further suggestions for the guidance of boys and girls, and for the institution of hostels and a bureau of guardianship.

The remaining sections of the report will be more useful to the general public than to medical readers, who may, however, be glad to have a handy review of facts and figures in connexion with infant mortality—ante-, intra-, and neo-natal, as it is now subdivided—and with the dangers of childbirth, with rather disproportionate accounts of the latest work on accessory food factors and of the useful experience of milk-farming at the Harper-Adams Agricultural College for the elimination of tubercle from milk, pointing in favour of the Milk Bill now before Parliament. On the subject of venereal disease the most alarming figures are given to show the danger of the "amateur prostitute" as responsible for two-thirds of the cases in certain military hospitals. The Commission favour a pronouncement by the Ministry of Health as to the advantages of chastity, and the duty of immediate disinfection for those who expose themselves to possible infection. The majority oppose the official use of packet prophylaxis in civil life as "neither desirable nor practicable." Compulsory notification and treatment of venereal disease, on the experience of the Dominions and of 40 out of 48 of the United States, should in their opinion have a trial; the questions of health certificates on marriage and of confidential certification of causes of death should now be reconsidered by the Government. On the subject of alcohol the Commission favours continued regulation of the liquor traffic on moderate lines; while similar counsels of moderation prevail with regard to reform of the divorce laws. A final section urges the development and education of young citizens for worthy parenthood, and points to the need of further inquiry into the physio-, psycho-, and sociological problems involved.

The book will be read with a feeling of satisfaction that the issues are cleared, but of profound anxiety as to the result of a cosmic struggle. Hope lies in the sound common sense of the British public, guided by the sound advice of the medical profession.

DAS HUNGERÖDEM.

Eine klinische und ernährungs-physiologische Studie. By Dr. C. MAASE and Priv. Doz. Dr. H. ZONDEK. Leipzig: Georg Thieme. 1920. Pp. 137.

FAMINE dropsy, which during the war was temporarily renamed war œdema and hunger œdema, is a disease that fortunately undergoes long periods of eclipse. Then it is wholly forgotten, and hence its literature is scattered and difficult to trace out. Such a book as Maase and Zondek have compiled is on that account of notable value. They have gathered into a single, small, and readable volume a very complete store of information upon one of the most interesting examples of a food-deficiency disease. The clinical description of famine dropsy is clear and good. The accounts of the state of the blood, urine, and digestive functions are exhaustive, and include almost everything that has been written on this aspect of the disease. The researches into metabolism include some most painstaking work in a branch in which the authors themselves have been pioneers. Maase and Zondek are not mere compilers; their contributions to the study of metabolism in famine dropsy have helped greatly in clearing some obscurities away. Even though elaborate investigation only proves the absence of striking abnormalities in metabolism, the investigation is no less valuable and necessary. In brief, Maase and Zondek give the following account of famine dropsy:—

> It is a form of dropsy which is produced by prolonged underfeeding upon a diet which is insufficient qualitatively and especially deficient in calories. Four cardinal symptoms characterise the disease—namely, œdema, polyuria, bradycardia, and asthenia. It is further distinguished by the remarkable absence of certain signs and symptoms—albuminuria, cyanosis, dyspnœa, and cardiac dilatation; also by the absence of the nerve changes seen in beri-beri, the skin changes of pellagra, and the spongy gums and tendency to bleeding which denote scurvy. The changes in the urine scarcely imply any abnormality in metabolic or renal function. There is a marked polyuria, which varies with an equally pronounced polydipsia. Chlorides are increased in the urine, and apparently depend upon an increased intake. Urea-nitrogen is low, and agrees with the low protein value of the diet. Ammonia-nitrogen and kreatin are increased, as in all forms of starvation where the tissue-protein is being disintegrated. In the blood there is hydræmia and hypo-albuminosis, an increase in kreatin and ammonia-nitrogen, and a great decrease in lipoids. As a rule, the degree of oligo-cythæmia is moderate (3 to 5 millions), the colour index is normal, and leucopenia is present.

To this point the authors bring us, and up to this point their book is a reliable guide. But the later and more illuminating researches which have been carried on in England and in the United States have either been too recently published or have been inaccessible to them. The subsequent chapters in our knowledge of famine dropsy must be looked for in the work of Harden and Zilva, or McCarrison in this country, and of Kohman, Denton, and Maver in the United States, not omitting that of Hindhede in Denmark, both prior to and since the war. In the history of the study of famine dropsy Maase and Zondek are unaware of the important contributions made during the Indian famine of 1877–78 by Cornish and by Porter, contributions which form the starting-point of the modern conception of the disease. Although we point out these limitations in the book under review, we give it our ungrudging praise for its completeness and accuracy as well as for brevity and clearness of style. Its bibliographies are good and the references correct.

SIGHT TESTING MADE EASY

Fourth edition By W WRIGHT HARDWICKE M D St And , M R C P , L R C S Edin London J and A Churchill 1920 Pp 80 5s net

THE author of this little book tells us that one of its objects is to enable the busy practitioner to test the sight of a patient and prescribe the necessary correcting glasses in the shortest possible space of time This aim it may be said to have accomplished We should have greater confidence in the result of the practitioner s prescription, however, if during his student days he had been given the opportunity of acquiring so much knowledge of the objective methods of examining the eye and its refraction as would render such a book as this superfluous It is, we believe, the practice of many country practitioners to refer their refraction cases to opticians The man who, not having any previous knowledge of the subject, puts his trust entirely in this book is not likely to do much better for his patients The advice given on page 16, to refer cases of heterophoria to an ophthalmic specialist, should not be weakened by laying down rules for the treatment of that condition (on pages 64–65) which are wholly inadequate But in the main the book is clear, and the student commencing his work in the ophthalmic outpatient department may be recommended to read it

ANTITUBERCULOSIS RECONSTRUCTION

By D P H , R C P S I Dublin and London London Maunsell and Co , Ltd 1919 Pp 38 6*d*

THIS pamphlet is as full of meat as it is concise it has obviously been written by a person with many years experience of all sides of the tuberculosis service He evidently finds it a service with many shady sides to it, with many abuses and much mismanagement In a chapter on sanatorium management he inveighs against the system of honorary visiting physicians, who reduce the status of the resident medical officer to little better than that of a house physician All the sanatoriums that have made a mark in the world were blessed, in his opinion, by having resident medical officers who were masters in their own house With regard to appointments, he quotes Télemaque "Talent? Merit? Services? Bah, belong to a coterie! In short, the system of management of English public sanatoriums is, he argues, fundamentally wrong The author does not confine himself to destructive criticism, and many of his recommendations are sound

The pamphlet is well worth reading and re reading by all in authority who are anxious to combat "the mismanagement, the petty jobbery, the petty oppression, the insular backwardness, all hidden with the pertinacity of a war time censor, hushed up by the familiar British conspiracy of silence " For there is truth behind the writer s vigorous protests

RAMBLING RECOLLECTIONS

An Autobiography By A D ROCKWELL, M D New York Paul B Hoeber 1920 Pp 350 $4

Dr A D Rockwell is perhaps best known to British medical men as the Rockwell of "Beard and Rockwell," which was for many years the premier treatise in the English language upon electro therapeutics, a position which it maintained until superseded by W E Steavenson's work on the same subject, which in its turn was amplified and eventually entirely rewritten by Lewis Jones

Dr Rockwell was born in 1840 at New Canaan Conn , so that he has well over 70 years of remembrance behind him In fact, he tells us that his earliest recollection is of walking about the house singing "Four years old next May ' His mother s maiden name was Comstock, a name well known to our fathers in connexion with Comstock's Natural Philosophy, for many years a deservedly popular treatise on both sides of the Atlantic Dr Rockwell gives us a charming picture of his childhood, a life which seems nowadays very far away The family physician was Dr Noyes, and Dr Rockwell describes how his grandfather paid the said Dr Noyes 25 dollars a year whether he was sick or well He used to arrive on horseback, with saddle bags containing a selection of nauseous drugs which were administered quite undisguised Blue pill was carried in the mass and converted into pills between Dr Noyes s finger and thumb as occasion required When Rockwell attained the age of 15 he obtained a situation as boy of all work to a New York firm of jewellers, but at the age of 17 he was sent to Kenyon College When 21 he began to learn medicine, studying at Ann Arbor and New York, graduating in 1864, and in the same year he received his commission as assistant surgeon in the Sixth Ohio Volunteer Cavalry seeing a good deal of service with Sheridan Being discharged in August, 1865, he began civilian practice and worked in conjunction with Dr Beard, whom he had previously known in New York These two men became the practical founders of electro therapeutics in the States, and very largely influenced the study in Great Britain They remained in partnership for eight years, when they separated, though always maintaining their friendship Beard could not have been an easy person with whom to get on, and was obviously a very original character, in whom a strong sense of humour made other qualities more acceptable

Dr Rockwell has an interesting chapter upon electrical executions, in the establishment of which method his evidence was a leading factor The rest of the book is chiefly made up of personal recollections of various characters, notable and otherwise, which are all, however, good reading As a record of a busy, useful life, and a picture of a fashion of things now long passed away, the book can be warmly commended

MUSINGS OF AN IDLE MAN

By R H FIRTH, K B E , C B , Colonel, and late a D D M S with the British Army in France London John Bale, Sons, and Danielsson 1919 Pp 360 7s 6*d*

THIS is a pleasant little book of musings upon a multiplicity of subjects, and is just the volume for anyone to keep by his bedside in case he be wakeful Not that we wish to suggest by this remark that reading the book will bring about ' an exposition to sleep but rather that the essays, being short and written in a pleasant style, need no particular mental effort for their due appreciation The author travels over a wide field—to use his own words, "the fields most frequented have been those of ethics, evolution, idiosyncrasies, manners, morals, mysticism, nature, philosophy, sociology, and even spiritualism ' He is evidently widely read, and has not forgotten his classics His views on his various subjects are always interesting, though we may not always agree with him For instance, when he says, on p 115, that the Romans "in exact proportion to their study of Greek paralysed some of the finest powers of their own Latin' the statement is certainly not true in the case of Cicero But we quite agree with his further remark that "some of the grandest, tenderest, and most sublime passages in our literature are made up almost exclusively of short Saxon words ' The Authorised Version and Shakespeare bear witness to this—e g , "Come from the four winds O breath, and breathe upon these slain that they may live ', or again, "Thy pomp is brought down to the grave, and the noise of thy viols, the worm is spread under thee and the worms cover thee ' Or take this from Macbeth —

> Thou sure and firmset earth
> Hear not my steps which way they walk for fear
> The very stones prate of my whereabout
> And take the very horror from the time
> Which now suits with it

JOURNALS

The Journal of Physiology Edited by J N LANGLEY Sc D LL D F R S Vol LIII No 6 pp 367–478 Cambridge University Press 1920 9s —Studies on the Capillarimotor Mechanism—I the Reaction of Stimuli and the Innervation of the Blood vessels of the Tongue of the Frog by August Krogh Certain experiments seem to point to a reconsideration of current conceptions concerning vaso-motor regulation and the mechanism of vaso motor changes The prevalent idea identifies vaso-motor changes with arterio motor—i e that the vaso motor mechanisms control the smaller arteries and arterioles and therefore largely regulate the capillary circulation so that the state of filling of the capillaries follows as a physical consequence from the general blood pressure and the state of contraction of the arteries and arterioles. Recent experiments show that the calibre of capillaries is not simply a function of the pressure of the blood coming from the arterioles, but that the capillaries have independent reaction, and may dilate and contract individually and independently of the blood pressure within their walls. Histamine and minimal doses of adrenalin have a dilator effect on capillaries which is independent of the nerve-supply, while the effect of these substances upon arteries is that of constriction. The author studied microscopically the reactions of the blood-vessels of the frog's tongue to mechanical, chemical, thermal, and electrical stimulation, and as the result of his careful experiments, assumes that the nerve-endings in the walls of capillaries and arterioles have a double function, being at the same time sensory and dilatory—i.e., inhibitory with regard to the vascular tone. For this view several reasons are assigned. It would appear that capillary tonus is only to a very slight extent—if at all—of a nervous nature. Experiments indicate that arterial pressure is unable to dilate capillaries to any appreciable extent or open them up when they are tonically contracted, while the venous pressure may be sufficient to fill them when relaxed in response to weak mechanical or chemical stimulation locally applied. The state of filling of the capillary vessels does not depend, therefore, upon the arterial blood pressure, but upon the degree of tonus or relaxation of the capillary wall. Local mechanical—by fine hairs—or thermal stimulation, or the application of minute drops of weak acid, cocaine, or adrenalin, may produce dilatation both of capillaries and arteries. With a strong stimulus the effects spread to an area greater than that stimulated. Urethane causes dilation of the capillaries without affecting arteries. The reactions of the vessels to local stimulation is abolished by cocaine. They are not affected by simple section of the nerves, but disappear when sufficient time is allowed for the nerves to degenerate. Probably the reactions are due to local axon reflexes of the antidromal type. Electrical stimulation of the lingual nerves was without effect on capillaries, but strong mechanical stimulation may cause very considerable dilatation of capillaries and arteries in the area innervated. Capillary tonus is not principally of nervous origin, but depends upon the supply of blood. The substance in the blood responsible for this action is unknown, but it is not oxygen.

The Changes in Respiration at the Transition from Work to Rest, by A. Krogh and J. Lindhard. The changes were studied by the use of a bicycle ergometer and a special respiratory chamber. The changes due to muscular work gradually return to the resting level when work is stopped. The oxygen deficit caused by the lagging behind of the oxygen absorption in the first minutes of work is not compensated during work, but may be determined quantitatively when work has ceased. When heavy work has ceased the respiratory quotient rises, often far above unity, and the increase is continued during about one minute and a half. This rise may be due to washing out of CO_2 caused by the fixed acids in the blood.

The Flow of Oxygen through the Pulmonary Epithelium, by J. Barcroft, A. Cooke, H. Hartridge, T. R. Parsons, and W. Parsons. The rôle played by the pulmonary epithelium in respiration has been a matter of controversy for over 30 years, one set of observers holding the view (1) that the oxygen passed by diffusion, the other (2) that it was transferred by a secretory process depending on the expenditure of energy on this part of the lung cell. The authors' object was to test the theory of oxygen secretion. If, as is alleged by Haldane and Douglas, the oxygen pressure in the alveolar air is, under conditions of oxygen-want—anoxæmia—lower than that in the arterial blood, the secretory theory may be regarded as proven. If, on the other hand, the pressure of oxygen on the two sides of the pulmonary epithelium are approximately equal, the question arises: Will diffusion account for the quantity of oxygen which experiment shows must pass into the blood in a given time? The conditions of the experiment were rather arduous and demanded prolonged self-sacrifice for science sake, for the subject of the experiment lived in a glass chamber for six days exposed to anoxæmic conditions, the anoxæmia being produced by a reduction of the partial pressure of oxygen to 84 mm. by increasing the percentage of nitrogen. On the evening of the sixth day a comparison was made between (*a*) the amount of oxygen in the blood as taken directly from the radial artery without exposure to air, and (*b*) the amount of oxygen in the same blood after it has been shaken with alveolar air of the subject. The comparison, as made with the subject at rest, was repeated whilst he was taking exercise, the quantity of exercise being measured. Had the arterial blood as withdrawn directly from the artery contained more oxygen than appeared in the same blood when shaken up at body temperature proof would have existed of oxygen secretion. The duration, maintenance, and degree of anoxæmia are all carefully described, as well as the methods of determining the oxygen in the blood, and the analyses of the final stage of the experiment, the operation on the radial artery, the collection of the blood, alveolar air, expired air, and the results obtained. (1) Under a condition of anoxæmia caused by living for six days in an atmosphere in which the partial pressure of oxygen fell to 84 mm., analyses were made of the alveolar air and arterial blood in man. The arterial blood *in vivo* contained less oxygen both during rest and work than did samples of the same blood exposed to alveolar air *in vitro*, at body temperature. (2) During work the quotient of the oxygen consumption and difference in oxygen pressure yielded a diffusion constant of about 100. (3) There was no self-reduction of the blood sufficient to invalidate the determination of the percentage saturation of the blood withdrawn directly from the radial artery.

The Cortical Paths for Mastication and Deglutition, by F. R. Miller. It has long been known that movements of mastication may be elicited in the rabbit by stimulation of the cerebral cortex. These movements are bilateral. This masticatory rhythm and deglutition can be elicited from the infracortical tracts as far posteriorly as the corpora mammillaria. Beyond this level both reactions cease to be evocable, because the fibres concerned have passed to their respective motor nuclei as "aberrant fibres." The steady jaw closure which replaces rhythmical mastication is caused by escape of current to the mandibular branch at its exit from the skull. There is no deglutition centre in the thalamic region, and a mastication centre there seems improbable. The infra-orbital tract for mastication and deglutition passes through the lower part of the internal capsule at the level of the posterior part of the caudate nucleus to the medial part of the pes at the level of the corpora mammillaria.

The Colloid-free Filtrate of Serum, by A. R. Cushny. When serum is filtered through a collodion membrane which retains the colloids, most of the other constituents, such as salts, sugar, urea, occur in the filtrate in the same proportion as in the original serum. The only exceptions to this rule are calcium and, possibly, magnesium, which pass through the filter in a lower concentration than exists in the serum. The non-colloid constituents other than calcium and magnesium are therefore in simple solution in the serum, while part of the Ca and Mg is probably in some form of combination with the proteins. Possibly the combined form in which Ca exists in the serum may account for its being in part excreted by the intestinal epithelium. No such combination as "ion-proteid" exists in the blood plasma, and the view that the proteins expel the CO_2 from bicarbonates is incompatible with the absence of such compounds. If filtration occurs in the kidney glomerulus the filtrate must be substantially identical with that obtained from serum by means of a collodion membrane.

Shorter communications include Action of Guanidin on the Heart of the Frog, by D. Burns and A. Watson. Guanidin salts (0·25–1·7 per cent.) produce primary cardiac acceleration, followed by prolonged and marked retardation of the beats, due to (*a*) vago-cardiac nerves and (*b*) pronounced vaso-constriction, with reflex inhibition. By the use of atropine and nicotine the point of action of guanidin was found to be a nicotine-like action on the sympathetic neurones.—The Effect of Injection of Guanidin on the Creatin-content of Muscle, by George M. Wishart. When administered intravenously or subcutaneously in cat and frog an inorganic salt increases the creatin-content of the muscles, which varies with the dose administered.—Non-medullated Fibres in the Spinal Ganglia, by Margaret E. Wilson. As it had been suggested that the non-medullated nerve-fibres described by S. W. Ranson were neuroglia fibres, the author using specific neuroglia stains finds no neuroglia elements in the ganglia.—The Determination of the Circulation-rate in Man from the Arterial and Venous CO_2 Tension and CO_2 Output, by G. Liljestrand and J. Lindhard, is somewhat technical, as is Pitch Discrimination in the Dog, by G. V. Anrep. In part this is an epicritic on an article in the Behavior Monographs by H. M. Johnson ("Audition and Habit Formation in the Dog"), criticising the experiments by the Pavlov Petrograd School on the auditory capacity of dogs. The Pavlov School maintains that the dog possesses fine auditory differential capacity as well as highly developed pitch discrimination. The experiments of Anrep deal largely with what Pavlov has called "conditioned reflexes" as applied to the salivary glands.

The Prescriber. Edinburgh: Thos. Stephenson. 2*s.* 6*d.*—The June number of this journal is devoted mainly to colloid therapy, and a very interesting series of articles appears, setting forth the place colloids are rapidly taking in general practice and their use also as antiseptics. The bibliographic summary containing references to the use of colloidal metals and non-metals in therapeutics will be found particularly valuable in bringing forward all that has been done on the subject, and the directions in which colloids are being used with the prospect of successful treatment.

THE LANCET.

LONDON: SATURDAY, JUNE 26, 1920.

An Emergency Grant to the London Hospitals.

AT a special meeting of the General Council of King Edward's Hospital Fund for London, held at St. James's Palace on Tuesday last, it was unanimously decided to make an emergency distribution of £250,000 out of the available general funds, in order to assist the London hospitals to meet their most pressing needs. The terms of the resolution were cordially approved by the KING, the patron of the Fund, to whom they were submitted, and who in a message of support added his desire that all societies and public bodies, on whom the obligation to assist the London hospitals in part rests, as well as all private individuals, should join in the effort to meet the emergency, "and thus ensure the continuance of the voluntary system." The Council's decision to make the large and immediate grant was unanimous after hearing the sound arguments of Lord DONOUGHMORE, who presided; but the Right Hon. JAMES WILLIAM LOWTHER, the Speaker of the House of Commons, and Lord BURNHAM, in pointing out that the working people of London did not seem to be aware of their responsibilities towards the institutions by which they benefited so largely, expressed a general view.

The Problems of Medical Education.

THE Report of the Education Committee of the General Medical Council upon medical education, with particular reference to the preventive aspects, led to the interesting debate by the Council in Committee which we published last week, and to the important declaration, contained in an ensuing recommendation, which was adopted by the Council, "that the questions which have been raised involve the revision of the whole curriculum in medicine." There is reason to suppose that the proceedings in the Sections of Medical Education and of Medical Sociology at the meeting of the British Medical Association, which commenced session at Cambridge to-day, will confirm the sense of this recommendation; and in this way the feeling that "something must be done," so general among all teachers for the past 30 years, may be replaced by the fact of something being done, and done quickly.

But he will not be so much a sanguine man as a shortsighted one who is expecting that any revision of the medical curriculum will settle the problems of medical education. Indeed, we may congratulate ourselves that, medicine being a science of constant progression and an art of undefinable inspiration and technique, new problems in the training of those who are to live by its practice will be ever arising. Medical education cannot be conducted on the system which kept the Chinese, despite their industry and acuteness, in worse than mediæval bonds until 30 or 40 years ago. An infinite elaboration of a settled pattern leads to sterility. Medical education must move with the scientific times, and as medicine calls to its assistance with greater intimacy more of the allied sciences, so will questions be more frequently raised as to how much of this or how little of that is it necessary that the medical student should know, if he is to fulfil his one duty, in any of its various subdivisions, of being the medical adviser of the people. Each time that new questions, over this large reference, multiply in number until teachers and taught are embarrassed, inspection will show that the medical curriculum requires revision; and certainly such a time has now arrived. Indeed, it was overdue before the war prevented any measures of remedy. That nothing was done during the war is a reproach which our educational authorities can bear, not only because it is an unreasonable one, but because they can fairly say that the factors concerned have been so changed that reforms put into action before the great upheaval would be found in practice unsatisfactory to meet the existing situation. But it is not a matter for congratulation that we can look back two generations and find that many changes which are being advocated in the curriculum were advocated at that distant period, even though they form only a part of the work which has now to be done. To-day, however, the General Medical Council, by consulting the various bodies with the right to grant degrees and diplomas, has received a mandate to act promptly in relief of the difficulties experienced at all medical schools. Since 30 out of 38 of these bodies replied to its questionnaire the Education Committee of the Council has been able to report in the light of broad and more or less concordant views. The Council may be said to have received in this way authority to proceed and certain general advice for its guidance.

While there are several suggestions made to the Committee for shortening the curriculum there are none for lengthening it. While there is an obvious feeling that an advantage would be gained were the minimum age of entrance to the medical schools raised to 18, there is no definite instruction as to the standard which should be reached at any entrance examination. The feeling is general that the last two years of school life could be largely devoted to chemistry and physics, and a pass certificate in these subjects accepted at the medical schools. This would greatly lighten the curriculum at one stroke, but such pass certificates must be within the reach of all medical students alike, and there are parts of the United Kingdom where the necessary instruction could not be received. We see that the old difficulties attend the very first two steps. While admitting that the science of medicine has increased in scope, and that therefore there is more for the student to learn, we are confronted with the fact that nobody thinks more time ought to be compulsorily taken in which to learn it—a view which we heartily endorse. Therefore overlapping must be abolished, redundancy pruned away, and, if possible, material, in the shape of students, must be received for the professional subjects more advanced in growth, if it is to reach a standardised height in a limited period. Waste of time may be avoided by ensuring that neither the ancillary subjects nor the directly professional subjects of anatomy and physiology are taught in compartments. A great improvement in the work of medical students and in their ability to pass sensible examinations, because they really know their task, will be ensured when the study of anatomy, physiology, and physics accompanies the student through the study of pathology, the teachers forming the connecting line. The full Report of the Education Committee is by this time in the hands of all the authorities of medical education; for our part we wish it was available for all practitioners, and for this reason mainly, that it *defines* what is indicated by "preventive medicine," the subject matter of the whole debate. Hygiene and public health are not in question. What is meant is the avoiding, the cutting short, the aborting of disease by the early recognition of its presence. It would indeed raise the standard of medical education if the student could be taught to detect incipient maladies, but such instruction must surely follow on familiarity with the grosser phenomena of established disease.

The Tropical Disease Prevention Committee.

THE well-worn proverb concerning honesty and policy has been criticised by many as basing a high aim on the low grounds of self-interest, and the fifth Mosaic Commandment is open to the same objection. In a work-a-day world both aphorisms find acceptance, and to all States and Governments, as well as to those responsible for large commercial enterprises, we would point out that those who contribute generously to the endowment of pure science will be rewarded by practical results of such advantage to themselves that their original gifts may truly be spoken of as "good investments." And in no sphere of man's work is this more true than in the study of the nature and causation of tropical disease. When once the nature and causation of the group of diseases comprehensively spoken of as "tropical" are known —but not until then—the true means of preventing, or, at least, of controlling them, comes into sight. While much has already been done in the patient investigation of tropical diseases, it would be idle to deny that we are still ignorant of the exact causes and mode of spread of many of them, or that there is still a vast field of investigation open before the problem of their successful control can hope to be solved. Great territories, not a few of them forming part of the British Empire, are still ravaged by leprosy, yaws, beri-beri, pellagra, plague, blackwater fever, bilharziasis, hookworm disease, filariasis, and other loathsome diseases; and in many cases the loss of man-power entailed by their prevalence is so great as to form a serious barrier to the progress of the State or the success of great commercial undertakings therein.

Any fresh attempt, therefore, to conquer the unknown in respect of these diseases must be welcomed. The Tropical Disease Prevention Committee has been formed with this as one of its objects, and Dr. E. T. JENSEN (71, Harley-street, London, W. 1) is acting as honorary secretary. It is composed, we are glad to see, not only of many distinguished specialists in the study of tropical disease and of representatives of the allied sciences of botany, zoology, geology, agriculture, and veterinary science, but also of leading administrators and pro-consuls in tropical lands and of the heads of great commercial houses interested in those countries. It has, moreover, an international character, and in the striking list of members appear the names of well-known authorities of French, Italian, Dutch, American, and other nationalities. The objects of the Committee are briefly explained in its subtitle, "a Committee to Encourage Imperial and International Research and the Eradication of Preventable Disease in Tropical Countries," and are more fully set forth in a pamphlet issued by the Committee. It is there pointed out that "there is no organisation, like the Rockefeller Foundation, in this country whose aim is solely or even principally that of the eradication of tropical diseases." The fact that the knowledge already gained by long experience in the fight against such diseases has not been generally applied, nor always in a reasonable and efficient way, is noted, and the need for immediate action is dwelt upon. The Committee rightly aims high. It is hoped to raise immediately a sum of £100,000, and it is proposed to begin work by undertaking a thorough medical survey of the Lesser Antilles. The advantages offered by small islands, as compared with vast continental areas, for such a survey are obvious. But the work is not to be confined to purely scientific research; it is hoped that the Committee will be able to apply, with the coöperation of local authorities, practical preventive measures, and for this purpose the Island of Barbados is suggested as a suitable field for an active campaign against ankylostomiasis, filariasis, pellagra, and leprosy. It is expected that the survey of the Lesser Antilles, which was first suggested by Dr. L. W. SAMBON, will occupy about three years, and that it will cost some £30,000. When that is completed other investigations will be carried out elsewhere, and it is hoped that the Committee and its work will be permanent and continuous. This must, of course, depend upon the support it receives from the public, and more especially from those who may be expected to benefit from the result of its labours.

Striking passages in the pamphlet prove the truly appalling economic loss in many tropical lands from preventable disease, and the contrast between vast engineering and labour enterprises aided by a rationally applied hygiene and such enterprises not so aided, is rightly and none too strongly emphasised. For example:—

> "During the construction of the Panama Canal from 1881 to 1889, the French lost by death 22,189 employees, at the rate of 240 per 1000. The death-rate from yellow fever varied between 7·3 and 20·6 per annum, and from malaria between 12·5 and 20·5. In the hope that African negroes might survive the climate, 1000 were imported; all died within six months. The same fate befell 1000 Chinese labourers."

The Americans took over the work in 1904; yellow fever disappeared in 1906, and the total mortality from all causes fell from the appalling figures just quoted to 8·1 per 1000 (in 1918). And again:—

> "In North Borneo, in seven hygienically managed estates, the average death-rate per 1000 was 10; in two less carefully managed, the death-rate was 43 and 72 respectively."

It will be among the objects of the Committee, we gather, to render impossible in future such ruthless slaughter of innocent individuals, to make universally known the lessons already learnt as to the methods of preventing many preventable diseases, and to widen the field of applied hygiene in tropical countries by research into the natural history of other diseases. These aims are as truly humanitarian as scientific, and as commercially promising—to descend once more to the levels of self-interest—as either. They cannot, we think, fail to appeal, and we gladly and warmly commend them, to the support of administrators in all tropical and subtropical countries, of the leaders of commerce in regions where disease is still a formidable obstacle to the full development of trade and labour, and, indeed, of all who are in any way interested in the future welfare of the earth's warmer zones.

The Rockefeller Benefaction.

The gift of £1,205,000 which the Board of Trustees of the Rockefeller Foundation has made to University College Hospital and Medical School and to University College, of which we gave the details in our columns last week, is the most magnificent endowment for education which this country has ever received. The gift is made primarily for the promotion of medical education and research, and the fact that it has been made to two institutions in London may be taken as a proof of the high place which London holds in the minds of the donors as a centre of medical training. The gift is not intended to relieve our charity for the sick poor of London. The Trustees, rightly in our opinion, conceive that this is not their business; they have never hitherto helped any medical charity in the States, but have limited their assistance, which has been on the most generous scale in that country, to the needs of medical schools and other educational establishments. The money is given for certain schemes of development on the part of University College Hospital and Medical School and University College which have received the approbation of the Rockefeller Foundation. These schemes include the addition of some 180 beds to the hospital, mainly for the purposes of the medical and surgical units which have already been established there, for the provision of an annexe to the hospital to house the new obstetric unit of 60 beds, and for the building and equipment of a new Institute of Anatomy at University College.

The unit system of clinical teaching, which has received strong support from the Foundation in the United States, was recommended for adoption in this country in the report issued in 1913 by the Royal Commission on University Education in London. The war prevented any action being taken, but at the end of last year, on the initiative of the authorities of the Board of Education, and largely through the good services of Sir George Newman, certain of the London medical schools were given the opportunity of setting up clinical units, the Board promising to pay three-quarters of the total approved expenditure in any one year. This offer was taken advantage of by several of the London schools, and units have now been established at University College Hospital and at four of the other medical schools—namely, those attached to St. Bartholomew's, The London, St. Thomas's, and St. Mary's. In a memorandum recently issued by the Universities Grants Committee, the body which now controls the grants made by the Treasury for the maintenance of the units, the essentials of this system are stated to consist of three units, which should be interrelated and inseparable, dealing with medicine, surgery, and obstetrics respectively. In each of these units there should be a director who would devote the greater part of his time to teaching, treatment, and research, competent to teach, of sound scientific training and with scientific imagination; with an adequate whole-time or part-time staff, with the control of beds and a proper out-patient department, with ample laboratory accommodation and post-mortem service and with adequate scientific equipment for clinical teaching. The units should work along with and supplement the ordinary ward services in which practical teaching will be carried on as before, but the clinical unit will deal more especially with scientific instruction and research. It was because they strongly approved of this system, and because they saw that it might fail for want of sufficient financial aid and adequate clinical facilities, that the representatives of the Rockefeller Foundation recommended their Board of Trustees to make this magnificent donation to one of the London hospitals.

The object of the gift is, first, funds for a building and equipment programme, to include additions to the hospital, so that the two units of medicine and surgery already established may have fuller clinical facilities, and that a third obstetric unit necessary to complete the whole scheme may be provided with a building and additions to the research laboratories in the schools; and, secondly, an endowment fund primarily for the needs of the units as regards their teaching and research. Until such time as the monies can be raised from other sources, for the maintenance of 120 of the new beds which are to be allocated for the use of the medical and surgical units the Rockefeller benefaction will be available. None of the money, however, is to be used for the maintenance of the new 60 beds in the obstetric unit, and it is for this reason and because of the larger maintenance charges which the increase in the size of the hospital and medical school will entail that the authorities of the hospital will be compelled, when the buildings are ready for occupation, to find a sum of approximately £20,000 at present value to meet this increased expenditure. The remainder of the gift is given to University College to build and equip a new Institute of Anatomy in which the necessary facilities for anatomical teaching and research will be provided in accordance with the scientific requirements of the time and for additions to the departments of physiology and pharmacology. The Trustees of the Foundation fully realise that their gift, large as it is, does not provide the whole of the monies needed for the complete fulfilment of the schemes of development laid before them by the authorities of the hospital and medical school, on which they have set the mark of their approval in so striking a manner. They trust, however, that this offering on their part may serve as an example to those in this country who have large fortunes at their disposal. And as they think that England should support its own medical charities, they intend that the money given by them shall be used for the advancement of medical education and research, and so, ultimately, for the welfare of mankind throughout the world.

In expressing our deep gratitude that this country should have received such a magnificent offering of goodwill from our brethren across the Atlantic, we may express the hope that the recipients will prove worthy of the great trust imposed upon them and will make such use of the opportunities afforded them that the benefits to mankind resulting therefrom may prove equal to the splendid generosity of the donors.

Annotations.

"Ne quid nimis."

INDUSTRIAL FATIGUE RESEARCH BOARD.

"THE good a man does lives after him" might suitably be chosen as a memorial epigram for the Health of Munition Workers Committee, who not only did much during their short life, but sowed many seeds which are only now beginning to grow to a harvest. One of these seeds was research into the workings of the human machine in industry. The growth of this research has never been allowed to stop; on the disbandment of the committee in 1917 it was kept alive by the Welfare and Health Section of the Ministry of Munitions until in 1918, when a body, the Industrial Fatigue Research Board, was set up to develop and extend investigation. The terms of reference to the Board, which is now attached to the Medical Research Council, are: "To consider and investigate the relations of the hours of labour and of other conditions of employment, including methods of work to the production of fatigue, having regard both to industrial efficiency and to the preservation of health among the workers."

We have now before us the first annual report[1] dealing with the work of the Board. From it some idea can be obtained of the difficulties experienced in organising this new field of research; in finding skilled observers to undertake investigations; in obtaining facilities for research; in fact, in constructing a machine for doing work which has never been done before with no precedent to follow. Other countries are watching to note success or failure, while labour on the one side and capital on the other have had at each stage to be conciliated and informed as to the value and importance of the work. In these circumstances the following statement is very satisfactory:—

> "Owing to the small amount of research on industrial fatigue which had been carried out when the Board was formed, they have been compelled to start their inquiries practically *ab initio*, with an investigating staff to whom, with a few exceptions, all the problems were new. In addition, the nature of the experiments generally involve observations over a long period, so that final results cannot be expected for many months after an investigation has begun. The initial difficulties, however, are now being quickly overcome, and although the work of the Board is still largely tentative, and must necessarily continue so for a long time, there is every ground for anticipating that progress in the future will be at a much more rapid rate than in the past."

The report shows the amount of spade-work which has been done; it is necessary work, but it does not appeal to the outsider, who looks for immediate results. Nevertheless, several useful reports have already been published, and there are clear indications that the output is likely to be considerably increased in the near future. Even as we write the first of a series of reports dealing with the textile industry has just been issued. Four investigations have been completed and reported upon, dealing with tinplate manufacture, shell-making, iron-founding, and industrial accidents. Nine other investigations, all of wide scope, are in progress, dealing with such industries as the manufacture of iron and steel, boots and shoes, the cotton industry, the silk trade, laundry work, vocational selection, and special statistical research. Six other investigations are approved for action as soon as the staffs are available for the purpose. The method of procedure followed is of some interest. Each investigation is entrusted to a special committee, of which there are 11 in existence, composed of not merely members of the Board, but also industrial experts, together with representatives of employers and workmen in the industry concerned. By this means full technical knowledge is obtained and also coöperation among masters and men. A staff of skilled investigators, visiting factories and carrying out laboratory research work, acts under the direction and supervision of each committee. As the work of the Board becomes more widely known applications for their services are likely to increase rapidly. Probably while foundations have been under construction advantage has been gained by lack of publicity. That day is nearly over, and the time is near when the value of the work to the health and contentment of operatives and to increased production for the community will call for wide recognition. Possibly practical application of the principles brought to light through the research work of the Board may be undertaken by such a body as the proposed National Institute of Psychology and Physiology applied to commerce and industry, the inception of which we recently drew attention to in these columns. Great Britain in this matter has established a lead, and there is promise of maintaining and increasing this lead. The scope of the work is intimately bound up with the sphere of preventive medicine; in "fatigue" the great James Paget saw the beginnings of disease, and its prevention cannot fail to react favourably on health. The possibility of establishing a theory of health to precede investigations into any theory of disease lies here.

THE DANGERS OF ASCARIASIS.

THOUGH serious complications due to the ascaris lumbricoides have from time to time been recorded, this most prevalent of all animal parasites is not usually regarded as a source of danger. In the *American Journal of the Medical Sciences* Dr. B. C. Crowell shows that the dangers are considerable and are overlooked because the word of the pathologist is seldom heard on the subject. Experience of several years in the necropsy-room at Manilla has led him to this conclusion. In the Philippine Islands as many as 62 per cent. of the population have been found infested, and in some places the percentage is much higher. Large numbers of worms may be present in the intestine, producing masses which cause ileus. Cases are recorded in which as many as 600 worms were passed in one day. Whether the ascaris can perforate the intact intestine is unsettled. Dr. Crowell has seen several cases in which it opened up a repaired wound of the intestine, determining fatal peritonitis. Hence the importance of using vermifuges in ascariasis when abdominal operations of choice are to be performed. Migration into the biliary passages must be more frequent than is indicated by the reports, as it is only in cases of operation or necropsy that the diagnosis is made. Leer has stated that ascarides are the second most frequent cause of hepatic abscesses. These are usually multiple and the pus is very foul. In one case reported by Dr. Crowell there were three large ascarides in the hepatic ducts, the largest of which extended to the surface of the right lobe of the liver. The common duct was distended and occluded by the folded bodies of two full-grown ascarides, and one protruded from the papilla of Vater. There were thrombosis of the splenic vein and acute hæmorrhagic pancreatitis. Migration of the ascaris to the stomach and œsophagus and expulsion by the mouth or nose is frequent. But the parasite may pass into any of the connected canals or cavities—nasal sinuses, lacrymal duct, Eustachian tube, larynx, and trachea. In the larynx it may cause alarming symptoms and even suffocation. Toxic and reflex symptoms, such as fever, nausea, abdominal pain, convulsions, tetany, delusions, symptoms simulating meningitis, may occur in ascariasis. Proof of the connexion is furnished by their disappearance after successful treatment of the infestation. In the horse and pig ascaris Flury found toxic substances (volatile aldehydes of the fatty acids) which cause irritation and necrosis. A nitrogenous substance which after subcutaneous injection in the dog causes death with severe hæmorrhages in the intestine was also found. Dr. Crowell has observed the case of a Filipino, aged 8 years, who was seized by vomiting, followed by pain in the chest and knees. Œdema, jaundice, melæna, hæmorrhage from the gums, and ecchymoses on the face and legs soon developed. The patient became very anæmic and died at the end of six days. The necropsy revealed 150 ascarides in the stomach and intestines, purpura hæmorrhagica with hæmorrhage into the stomach and intestines, and epicardial, pleural, retropleural, and retroperitoneal hæmorrhages. Another source of danger is the larvæ of the ascaris. It has recently been shown by Major F. H. Stewart, I.M.S., and others that on administering the eggs of ascaris suilla to the pig, rat, mouse, or guinea-pig they hatch in the intestine, and the larvæ enter the blood stream, pass through the liver and heart to the lungs, where they migrate from the capillaries into the alveoli, and thence through the bronchi and trachea to the pharynx. During this process pneumonia may be set up. There is reason to believe that similar changes may be produced in man by the ascaris lumbricoides.

---

THE MACALISTER TESTIMONIAL FUND

THE date of the presentation of the cheque, arising out of the generous response to the fund organised for the purpose of marking the very exceptional services of Sir John MacAlister to the Royal Society of Medicine during more than 33 years, has been fixed for Wednesday, July 7th, in the Barnes Hall, at 4.30 P.M. The ceremony will be performed by the President, Sir Humphry Rolleston, K.C.B., and will precede the business of the annual meeting, which will be held at 5 P.M. The fund will be finally closed on Saturday, July 3rd. The honorary treasurer is Sir W. Arbuthnot Lane, 21, Cavendish-square, London, W. 1.

FUEL REFORMS IN THE HOME AND FACTORY

THE Public Information Branch of the Ministry of Health has published an interim report on Smoke and Noxious Vapours Abatement. The report sets out much to which we have given publicity for a good many years; we cannot, indeed, tell the story better than by reference to our own columns. We asked in an annotation in THE LANCET of September, 1895, whether the Smoke Nuisance Act was properly enforced. Since asking that question much good work has been done in regard to smoke abatement, and the Coal Smoke Abatement Society, under the ægis of Sir William Richmond and Dr. H. A. Des Vœux, came into being. This has since organised an active movement under the able secretaryship of Dr. J. S. Owens, which culminated in the formation of an Advisory Committee on Atmospheric Pollution to the Meteorological Office. In the early part of 1910 Dr. Des Vœux, the honorary secretary of the Coal Smoke Abatement Society, and Dr. Owens consulted our Laboratory in regard to making some experiments in the direction of estimating the contents of the London atmosphere at regular intervals over a period of a year at various stations in the metropolitan area. A scheme was eventually formulated, and the first series of observations were made on June 13th, 1910, and the report which appeared in THE LANCET of Jan. 6th, 1912, on "The Sootfall of London," attracted considerable attention. In March, 1912, a conference of delegates was held at the International Smoke Abatement Exhibition at the Royal Agricultural Hall, and it was resolved that steps should be taken to secure the general adoption of a standard method for the measurement of atmospheric pollution by smoke and the other products of combustion and dust. A Committee was appointed, our Laboratory Director being one of them, and the methods originally adopted in THE LANCET Laboratory were received with favour by the Committee with subsequent modifications. The Committee with commendable activity got into a practical stride and was able to secure 28 observation stations throughout the country, with the result that on Oct. 24th, 1914, we published a first series of records received from these stations in regard to the insoluble and soluble matter collected in the rain caught in a standard gauge. The results obtained have been recorded under the heading of "A Monthly Record of Atmospheric Pollution" steadily ever since in our columns, and the work and publication continue.

It is clear from this interim report of the Committee recently appointed by the Ministry of Health that the statistics we have consistently published have convinced public authorities of the waste of and injury to health, fabrics, and vegetation caused by the burning of coal in the domestic dwelling and in the furnace of the factory. Its recommendations might have been made many years ago, though fresh questions have now arisen in regard to new housing schemes. Broadly speaking, the Committee rules out the open coal fire and suggests a coke-fired boiler or gas for the domestic service and also in grates. It regards a central hot water supply as practicable, but makes no further suggestions upon this point. It admits that the whole subject of hygienic and scientific heating deserves a very much greater measure of public attention than it has hitherto received. The report is disappointing from the view of further action, and the conclusions are not followed by recommendations. Gas for the present seems one way out, but we must have it cheap and with an effective thermal efficiency, which we pointed out years ago.

THE FEES OF MEDICAL REFEREES

LAST week Sir Herbert Nield asked the Home Secretary whether he would improve the scale of fees prescribed for and payable to referees and assessors under the Workmen's Compensation Act, 1906. Mr. Shortt replied that the matter would be considered with due regard to all relevant circumstances after the Departmental Committee, which has been inquiring into the working of the Act, has made its report. The relevant circumstances in question can be stated in a few words. The fees when prescribed were on a low scale, having regard to the responsibilities of the work, while the compensations payable to workmen under the Act have considerably increased during the 14 years of legislation. Further, the payments to medical men under the National Insurance Act have been augmented, and one of the arguments for this increase is to some extent applicable to the case of medical referees and assessors—namely, that the increased cost of living implies the necessity for higher salaries.

THE ACTION OF ETHYLIC ALCOHOL ON THE ORGANISM

SOME interesting observations on this subject have recently come to us from the University of Cordoba; they are published by Professor V. Ducceschi in the *Annali d'Igiene* for February. The increased consumption of alcoholic drinks lately noticed in Italy, and probably not confined to any one of the countries where there are no restrictions on sale, has brought into prominence the question of anti-alcoholic prophylaxis, and has increased the interest felt with regard to the mechanism of the action of alcohol on the organism. Professor Ducceschi undertook a series of experiments on dogs in reference to changes produced in the quantity of lipoids in the blood by alcoholic narcosis. He found the cholesterin was almost doubled by the repeated administration of efficacious doses of alcohol. This hypercholesteræmia was the sequela of the state of narcosis; in fact, in two dogs in which the blood was analysed before administering a large dose of alcohol, who were two hours later in a condition of profound narcosis, no appreciable change in the amount of cholesterin was noticed. It was also found that the daily administration of large doses of alcohol for a period of about six weeks caused an increase in the blood of about 50 per cent. in the fatty acids and 33 per cent. in the lecithin, and it was further noticed that if the administration was suspended the amount of fatty acids and lecithin was not materially reduced in the succeeding seven days. Observations were also made on 120 individuals, half of whom were abstainers and the others habitual drunkards; in the latter Professor Ducceschi found a decided increase in the cholesterin in the blood compared with the former. With regard to the action of alcohol on the tissues it was found that in the dogs experimented on the amount of total fats in the liver was increased by 300 per cent. and the cholesterin by a small amount. In the suprarenal capsules there was a slight increase in the total fats and a diminution of about 40 per cent. in the cholesterin. There were no definite changes in this respect in the kidneys or testicle. A state of inanition favoured the changes in the lipolytic index of the tissues produced by alcohol. From these observations and experiments we are drawn to the conclusion that the animal tissues are adapted for existence in a watery medium in which the fixed constituents of the cells, and especially the lipoids, are practically insoluble. The introduction into the blood of substances with a solvent capacity, and having other physico-chemical properties fundamentally diverse from those of water, such as alcohol, ether, and chloroform, necessarily disturb the static and functional equilibrium of the tissues, changing the relation of solubility between the blood and the tissue elements. This disturbance is shown by the immediate but transitory phenomena of intoxication and narcosis, and, when the action of the poison is intense and prolonged, by the slow processes of adiposis, lipoidolysis, degeneration, and final sclerosis.

MEDICAL INSPECTION OF HIGHER GRADE SCHOOLS.

WE commented in THE LANCET of May 1st (p. 973) on the new regulations for the extension of medical inspection and treatment to children in secondary schools. In the June issue of *The Journal of Education and School World* an article by Dr. A. A. Mumford, medical officer of Manchester Grammar School, discusses the requirements of medical inspection in these schools. He points out that the Board of Education Circular 1153 on the subject offers no new suggestions as to the lines of examination to be followed, beyond those already in use in the public elementary schools, with the exception of an additional note as to fatigue generally. He maintains that medical inspection in the secondary schools must differ radically from that in force in the elementary schools in that the children are selected more or less from a section of the population inspired by a higher purpose than that of merely conforming to the rules of enforced attendance. The higher grade scholars do not suffer greatly from the defects found among the elementary school children, and when they do they are, as a rule, promptly put under proper treatment. Something more, he insists, is necessary in the secondary school examination than merely finding, tabulating, and treating gross physical defects. If the medical inspector is to be of real use in the school he must be prepared to help the teacher to stimulate the capacity of the child for the prolonged mental effort involved in examination ordeals. The effect of this mental effort should be accurately estimated, and the specific causes of fatigue, such as long distance journeys to school, improper feeding arrangements, and various other causes contributory to fatigue thoroughly and scientifically investigated. The manometer fatigue test and the spirometer, both found useful by the Air Force during the war, should be used at these examinations. As Dr. Mumford points out, inflation and deflation chest measurements are misleading and inaccurate gauges of a child's physique or vital capacity. While entirely agreeing with Dr. Mumford's conception of medical inspection in secondary schools, we think that the Board is following the wisest and most helpful course in merely outlining a scheme for these examinations and leaving it to individual authorities to supplement it as they think fit. Unfortunately, really good work is likely to be hampered by the necessity for returns and schedules exactly similar to those used for elementary schools.

It is suggested that a Research Department at the Board of Education is urgently needed to deal with these and other findings, as it is only in the hands of specialists that groups of figures can be made to yield useful information. In the hands of the ordinary official they become valueless, and his attempt to deal with them waste of time. As a plea for the establishment of this Research Department, Dr. Mumford points out that although medical inspection has been in force in the elementary schools for the last ten years, in spite of the roseate reports of local school medical officers we are still without trustworthy information with regard to the total effect on national physique of cooping up our children in the present school buildings during the most susceptible period of their lives; and we must agree that the scientific results which have been obtained are negligible. If a Research Department, in addition to helping to settle such questions, is to deal a blow at the system which crams a mass of examination detail into the adolescent boy and girl at a period when the whole metabolism of mind and body is in a sensitive state of change, we are strongly in favour of its establishment. The general health of many a man and woman has been damaged by home study and the mental endurance entailed in working for examinations. Then, too, apart from the wholesale lowering of the national physique, the present examination system, by a process of elimination, is segregating to the professional classes what can be most simply described as the "examination brain"—by no means the highest type of mentality, and certainly not the most desirable. Anything that will mitigate the present evils of the examination system will be a national asset. It must be remembered that tests of industry and capacity are necessary. Examinations cannot be abolished, but educational methods should remove their dangers.

RAT REPRESSION.[1]

DURING the war, when not only the health of the armies but the food-supplies of the nation became matters of vital importance, the danger of the rat both to the health and well-being of the community, military and civil, began to receive the attention it deserves. The Rats and Mice (Destruction) Act of 1919 put upon the citizens of London the responsibility of taking steps to destroy rats on their premises and of taking reasonable measures to keep the number of vermin in check. Dr. Howarth's Report commences with an account of the natural history and habits of rats, and tells how to distinguish the brown from the black rat. Next are given some useful hints as to the best methods for making buildings proof not only against the ground-living and burrowing brown rat, but also against the agile and acrobatic black rat. The Report warns the reader to protect all food-supplies—including any waste foodstuff thrown away—from rats, and might well lay more stress on this, possibly the most important of all measures for rat repression, since the birth-rate of rats is practically dependent on the available food-supply. A sound motto to print on the top of any anti-rat propaganda would be: *No Food, No Rats.*

When the practical point is reached as to how actually to kill rats one becomes at once suspicious from the very number of different methods suggested. When in a pharmacopœia 50 different drugs are recommended to cure one disease, it is pretty certain that little confidence can be placed in any. Several types of trap are described, all no doubt good for a short while, but experience shows that no trap is of much use in any one place for more than a few nights, and a change of type of trap should be made frequently in each locality. Possibly the best method of trapping is by the use of lithographer's varnish spread on cardboard, on which the rats become as hopelessly involved as a fly on a fly-paper. Of poisons barium carbonate and squill (*scilla maritima*) are the best and the safest. The much-advertised viruses are discussed in the Report at considerable length, and as usual are voted against. Their killing powers are doubtful, except in certain isolated rat colonies, and there seems to be no question that they may become a danger to the health of human beings. It is still hoped that some specific infectious disease may be found that can be introduced amongst rats which may kill these rodents and yet be harmless to human beings. A very ingenious suggestion has been made by Rodier that by increasing the relative number of male rats the domestic felicity of these animals may be so upset that there will follow a marked diminution of the birth-rate.

---

[1] A Report on Rat Repression in the City. By Dr. W. J. Howarth, C.B.E., Medical Officer of Health, City of London. 1920.

This theory is justified by observations made among domestic animals and birds, when the number of males in a flock or herd has been increased the birth rate has invariably fallen, so that by destroying all female rats caught and releasing all males a desirable result might be brought about On the whole this Report is a very interesting and useful synopsis of what is known of rat repression

ANCIENT SURGICAL INSTRUMENTS

OUR attention has recently been directed to a pamphlet by Mr S Holth, of Kristiania Norway on Greco Roman and Arabic Bronze Instruments and their Medico Surgical Use It is a valuable supplement to Mr J Stewart Milne's Surgical Instruments in Greek and Roman Times issued at Oxford in 1907 Mr Holth purchased a series of instruments at the sale of the collection of antiquities from Syria and Palestine, once the property of Baron Ustinoff All the surgical instruments are of bronze excepting the silver handle of a knife, which bears an inscription in Greek, *Θές με, κλέπτα*, ' Put me down thief Lucian alludes to surgeons who put pretty gold and silver handles to instruments which they did not really know how to use Mr Holth figures a Roman steelyard such as Milne described, and does not, like Milne believe that it is an interloper, never employed by the profession for classical doctors weighed the drugs which they purchased wholesale being their own apothecaries A spoon spatula of Arabic origin bears it would seem its maker's name In only one other instance, related by Milne, is such a name found on an antique surgical instrument and it is well known to those who study British medical literature that makers cut trade marks and not their names on their wares until the days of George III Mr Holth's spoon spatula probably came from Palmyra, and was made in the days when the Arab Caliphs ruled in Syria Once more, as in the case of the steelyard, Mr Holth finds another contrivance similar to a like instrument in Mr Milne's series, and does not believe that it is an interloper It is a long needle made for the weaving of fishing nets, the author maintains that this needle deeply forked at each end was used to keep suture threads carefully wound up, and so always ready for use Mr Holth also describes an Arabic couching needle and a sharp spoon, the stem of which bears a scale to measure the length of fistulæ and the depth of wounds The author believes that it is practically a millimetre scale, used by some Roman surgeon ages before the metrical system was introduced by the Constituent Assembly of France at the beginning of the Revolution

CLEAN MILK

WE have dealt with the question of the supply of clean milk and its consummation to the point of fatigue The reasons for the clean supply being considered a practical necessity have long ago been amply substantiated It is difficult to understand why there should be any delay in this matter in view of the scientific evidence long placed before us in regard to the filthiness of milk supplies in general the refinements of bacteriology apart, it is enough to witness the dirty routine of the milking of the cow to make us insist on the universal adoption of superior methods in this direction We have before us a well studied and reasoned consideration of the whole question in a report published by the Research Institute in Dairying of University College Reading The authors of the report, which is entitled A Study of the Factors Concerned in the Production of Clean Milk [1] (Part I), are Edith G Knight, Kathleen Freear and R Stenhouse Williams We realise the difficulties of introducing *reforms* into the existing methods of the dairy farm and of convincing the farmer of the real prejudice to life and health which dirty methods of milk production may well involve But if, as this report shows intelligent and interested labour, aided by special appliances and appropriate buildings will secure a remarkably clean milk of good keeping quality with very low bacterial content the remedies are in our own hands The authors point to a perfectly simple and practical procedure where the application of scientific methods and strictly technical procedure are hardly needed Rigid cleanliness is regarded largely as their substitute, which includes the practice of the daily tub Science has most definitely shown which road to take and common sense should do the rest

THE LOSS OF WILLIAM OSLER

WHILE the country of his birth may be justly proud of having produced a great man he really belongs to the world and to all time Such a man was Osler and the minute of the Executive Committee of the Federation of American Societies for Experimental Biology in Cincinnati drafted by Dr C H Bunting is one of the many special tributes to the memory of Osler which can be paid by all of us to a leader in every sphere of scientific and social activity The minute runs —

> In the death of Dr Osler the medical profession has suffered an immeasurable loss Belonging to no cult or age or clime but descended in direct line from Hippocrates he was master of the art of medicine in its purest form As a teacher he was again master painting with broad strokes pictures of disease never to be forgotten by the student An investigator and an inspirer of investigation a worthy counsellor of brother physicians a delver into the history of medicine and an ornament to its letters and withal so human and of such rare personal charm as to be beloved of all who came in contact with him Such was the man we mourn We grieve not only for the loss of leader and friend but also that death overtook him in the very shadow of the great conflict which had brought him so great personal loss and sorrow and robbed him of the mellow years which were so fully his due

MEDICAL INSURANCE AGENCY

AT a *meeting of the Committee of Management of the* Medical Insurance Agency held at 429 Strand, W C , Dr G E Haslip, the chairman, presented his report for the year 1919 together with the balance sheet of the Agency for the year ending Dec 31st 1919, from which it emerged that while the expenses have increased the Agency is now self supporting and the business transacted in the year has been the largest yet done Steady progress has been made in accident and fire business and the income from all sources was £750 in excess of the income of 1918 The income earned showed an increase which was not only sufficient to meet the increased expenditure, but to continue the £1000 grants to medical charities and still leave a balance of £32 unallotted for the year The total sums distributed to medical charities up to the end of 1919 were £5 400

The report runs —

> 'In commissions and other sums earned by the Agency the three principal sources of business—life motor car and accident insurances—each show marked progress especially the former This is a satisfactory feature as life business is the most steady form of income in so far as that once a policy is negotiated until it becomes a claim by death or maturity it represents an annuity to the agency The number of new policies completed during the year totalled 63 as against 25 and 15 in the two previous years This is the highest number yet reached Motor car insurances showed steady progress and the commissions are up some £200 (All motor car premiums have been increased as from January of this year 40 to 50 per cent on pre war rates)

During the year £960 was returned in rebates to the insured being £280 more than in 1918 The sum *returned to the profession in rebates now amounts to* £7000 *The report of the chairman and the certified* balance sheet having been received and approved, the further grants to medical charities were discussed On the motion of the chairman seconded by Dr F A Gibbons it was resolved that out of the surplus funds of the Agency the following interim grants of £457 10s to medical benevolent funds be made —

Royal Medical Benevolent Fund	£150
Royal Medical Benevolent Fund Guild	150
Epsom College Benevolent Fund	157 10

As a result of this distribution the total sums allocated to medical charities have reached £5877 10s A booklet describing the work of the Agency and the advantages of insuring through it has been prepared, and this and all other information can be obtained from the Clerk *to the Agency*, Mr P N Adamthwaite, 429 Strand, London, W C

ROYAL INSTITUTE OF PUBLIC HEALTH.

BRUSSELS CONGRESS.[1]

THE inaugural meeting of the Annual Congress of the Royal Institute of Public Health at Brussels was held on May 20th, with Viscount SANDHURST in the chair. After short addresses had been given by representatives of the various countries, Major-General GORGAS was presented with the Harben gold medal.

The Harben lectures on Antigens and Antibodies from the theoretical, diagnostic, and therapeutical points of view were delivered, in English, by Professor MAURICE NICOLLE, of the Pasteur Institute, Paris.

Section of State Medicine.

This section was opened by an address from Lord DAWSON, the President, who gave a résumé of the report of the Consultative Committee on the Future Provision of Medical and Allied Services.

Venereal Diseases.—An excellent paper on the Legislative Control of Venereal Disease was read by Surgeon-Commander JOHN STODDART, who said :—

> The only measure we have at present for controlling venereal disease is the prevention of quack practice, and the prohibition of sale of anti-venereal drugs generally (V.D. Act, 1917). Legislation of a medical nature should not be punitive so much as restrictive in the case of the mentally deficient, the incorrigible, or the hopelessly infected. Punitive clauses figure in the proposed divorce laws and in laws that control sexual offences, but these are deterrent laws, to prevent crime and not administrative in function to banish venereal disease.
>
> Administration aims at obtaining: (1) Compulsory treatment for the infected. (2) Some method of statistical record such as notification. This is in general use in the U.S.A. in a modified form, also in Australia, and works well. The name is withheld so long as the patient attends for treatment; the medical registrar is a State official, not a local practitioner, so that no resentment is felt by the patient; heavy penalties are exacted for divulging secret information. (3) The compulsory medical examination of suspects. This figures in the Sexual Offences Bill now before Parliament.
>
> Some of the colonies restrict those suffering from communicable venereal disease from employment involving the handling of food, the manufacture of certain articles—e.g., cigars; also from hairdressing and the nursing of children. Probably the British would not submit to such interference with their liberty as is involved in the American attempts at the State suppression of prostitution. A compulsory medical certificate before marriage is required in certain States of the U.S.A., and is proposed in Austria. Legal privilege to medical men will be necessary if he is to be empowered, as in South Africa, to inform the parent or guardian of a future bride or bridegroom if the other party is to his knowledge suffering from venereal disease in a communicable form. But we want one comprehensive measure dealing with venereal disease, not several, placed on the English Statute Book.

Cancer.—A paper on Deaths from Cancer in Ipswich since 1841 was read by Dr. A. M. N. PRINGLE, who considered that the apparent increase of deaths from cancer since that date was not real, and that the increase had really occurred only in its recognition.—Dr. J. C. MCWALTER held that cancer mortality had increased, and that the Congress should mark the beginning of an anti-cancer campaign; he emphasised the importance of an efficient public dental service in this connexion, and to avoid the irritation and toxæmia resulting from carious teeth.

Section of Municipal Hygiene.

Sir LESLIE MACKENZIE chose as his presidential address the subject of the Past, Present, and Future of Municipal Hygiene. Various papers were read on the sanitation of Brussels and Belgium generally.

Dr. R. WYBAUW (Spa) broke fresh ground in his paper on the Hygiene of Spas.

> He considered that especial attention should be paid to the sanitation and hygiene of health resorts, visited as they are by many convalescents who still carry infective organisms, or, being weaker than normal persons, are more receptive of infection. Spitting should be prohibited. The Government should make itself responsible for the hygienic precautions necessary in the construction and maintenance of medicinal mineral-water supplies; the boring must reach solid rock, the perimeter of the spring at its surface must be kept covered; no vessel should be dipped into the water; all glasses should be sterilised by steam in the vicinity of the spring. The condition of the baths is not always satisfactory at continental spas. The bath must be made of a material easily cleansed; wood should only be permitted in the case of mud-baths. The rooms should be large, well ventilated, and admit as much sunshine as possible; heavy curtains should be abolished. The laundry of a bathing-establishment should be as perfect as that of an ideal sanatorium. Exported mineral water, from the moment it leaves the spring till the sterilised cork is put into the bottle, should not come into contact with any non-aseptic surface or with the hands of a worker.

Tuberculosis.—A discussion on the Administrative Control of Tuberculosis was opened by Dr. R. VEITCH CLARK (Croydon). It was generally agreed that greater accommodation was wanted for advanced cases, but the difficulties of making this provision were emphasised by the speakers. It was stated that one of the London metropolitan boroughs had endeavoured to unite with its two neighbours to provide a large dwelling house for this purpose, but that the scheme broke down, partly owing to the difficulty of finding a suitable house without damaging the value of the adjoining property by numerous funeral processions. The final blow to the scheme was the insistence of the London County Council that the selection of the cases for the home should be made by its own medical officers.—Dr. HYSLOP THOMSON (Herts) suggested that the advanced case should be housed in the same institution as the early and chronic case, separate blocks being provided for each class of case. A separate entry should be provided for the advanced block, and the funerals conducted in such a manner as not to attract the attention of the other patients.—Dr. J. CROCKET (Glasgow) was not in favour of the village settlement as a separate entity; the patients still required a considerable degree of medical supervision, and the settlements should be established on the fringe of the sanatorium grounds.—All the speakers were agreed that farm work would be found too hard; lighter occupations, such as horticulture and basket-making might be taken up. The patients should always be paid for their work, even if the payment was in reality a subsidy, since payment acts as an incentive to industry. Several speakers commented on the apparent failure of the sanatorium.—Dr. HYSLOP THOMSON ascribed the disappointing results to the absence of a uniform standard of institutional treatment. There was very little uniformity of practice in respect of rest and graduated exercises in relation to the patient's temperature. While in one institution a patient was kept rigidly at rest if his temperature taken in the mouth reached 99°F., in another he would be put to work.—Dr. J. R. KAYE considered that a patient was often quite able to work, and benefited by work, when his temperature was slightly raised. Workshops were being provided in sanatoriums in the West Riding, but he found it was difficult to get men to work. He pointed out that the proposal to relax the restrictions in training colonies for tuberculous discharged soldiers would be prejudicial to their welfare; these men needed supervision and control to the same extent as the civilians. The provision required at present was not so much new curative establishments, but ordinary dwelling houses. Overcrowding was increasing; we were making cases of tuberculosis.

This view was supported by Dr. McFadyen's statement at the discussion on housing. He pointed out that the death-rate from tuberculosis in Letchworth Garden City last year was the lowest in Hertfordshire.

Dr. WYBAUW feared that if we were to spend enormous sums on sanatoriums and village settlements we should have no money left on keeping healthy those who are not yet tuberculous.

Professor E. SPEHL (Brussels) made some novel suggestions with regard to the selection of the pre-tuberculous.

> He determined the vital capacity of persons over 7 years of age by using Verdin's spirometer; for children below 7 the circumference of the thorax was used as a guide. The product of either of these figures and the weight divided by the height gave an index, the vital quotient. Indices affording information as to the respiratory function were afforded by dividing the vital capacity by the height and weight respectively. Average values had been worked out for persons of different ages; also for groups of soldiers, non-tuberculous civilians, and consumptives. From the information so obtained Professor Spehl constituted standards for selecting those of weak constitution who require either more food or breathing exercises, and those of very weak constitution, the pre-tuberculous, requiring open-air treatment.

Housing.—Dr. E. W. HOPE (Liverpool) and Lieutenant-Colonel F. E. FREMANTLE contributed to a discussion on housing.

Dr. G. Q. LENNANE (M.O.H., Battersea) said that a scheme for building on the small sites available in

---

[1] We regret to have been unable to publish the account of this Congress while the work was proceeding.

Battersea had been sent to the Ministry of Health more than a year ago, but was still awaiting the Minister's consent to commence building

He thought the law as regards houses in an unsatisfactory condition of repair placed authorities in an apparently strong but really weak position If the houses were not put into repair, the Council, to enforce Section 28 of the Housing Act, 1919 would have to create a Works Department, and make a considerable outlay for which they would receive an inadequate pecuniary return He considered the financial provisions of the Act to be very inadequate, and the institution of Housing Bonds financially unsound The Government should have financed the scheme instead of throwing the burden on the locality

Dr Hope considered that in view of the large increase of wages it was only reasonable for the working man to pay more rent Dissatisfaction was expressed with the restrictions of work placed upon building by the trade unions

Councillor WILLS (Bermondsey) said that if the authorities as landlords set out to build a good house that would last 100 years they would easily get their money back in the shape of rent.

He reminded the meeting of the remark of Lord Leverhulme at the inaugural ceremony, that it was not the first persons over the bridge that should pay in the shape of toll the whole of the cost of the bridge The Ministry was continually reducing its own standards in his council he had called attention to the fact that in plans for four roomed flats in Bermondsey the Ministry wanted a fireplace taken out of a child s bedroom, and, unfortunately, the majority of the council had agreed Councillor Wills spoke strongly in favour of the resolution, subsequently agreed on by the section, "that this meeting is of opinion that all houses built in the future must not be of a lower standard than that originally given in the recent manual of housing, and shall not be lowered for reasons of economy

Female Labour and Infant Hygiene.

The meetings of this section were particularly well attended by our Belgian colleagues The Presidential address of Mrs. SCHARLIEB was followed by a paper by Lady RHONDDA pleading for the employment of women civil servants as administrators in the Maternity and Child Welfare Department of the Ministry of Health.—Lady ASTOR drew a vivid picture of the evil effects of alcohol, especially on the poorer classes of the community —Lady BARRETT read a suggestive paper on the added strain of pregnancy on a tired woman and the desirability of diminishing her excessive work Lady Barrett advocated the provision of communal kitchens, dining rooms, and laundries, central heating and electric light in the home, also a water supply to each floor. Incessant work, noise, worry, and anxiety were disturbing factors in pregnancy. Day nurseries should not refuse the children of mothers doing domestic work at home. Professor C. S Sherrington had shown that six hours' work daily results in the optimum output, and this period should be aimed at for the mother.

Considerable discussion arose on the merits of the creche. The experiences of the medical officer of the creches at Liége were quoted. Owing to the excessive mortality among the children attending he had protested against their continuance Several Belgian speakers considered them an unfortunate necessity under present conditions.

Factory work for women —There was much difference of opinion as to the desirability of factory work for women Mdlle. ALICE WILLEMS, Mdlle. v. CAPPE, and others advocated legislation prohibiting factory work to married or pregnant women, while Lady BARRETT, Lady RHONDDA, and Dr. W. CULLIS considered that a woman should be left free to make her own decision on the point —Dr. C. W. HUTT (Richmond) suggested that the employment of the married woman with children and of the pregnant woman were separate problems and should not be discussed together. The effect of industrial employment on infant mortality and on abortion were discussed, the practicability of a 4 fr a day State subsidy to mothers was negatived. Finally the section voted for the gradual suppression of the work of married women by every means possible short of legal prohibition

Mothercraft —Mrs H. B. IRVING considered that the civilised mother had three elementary rights · (1) free medical advice and treatment; (2) to suckle her child and to receive instruction in mothercraft; (3) to live in decent surroundings and not to be compelled to work outside her home. Much difference of opinion followed as to the period of life at which mothercraft should be taught —Dr. HUTT thought that only the broad outlines of mothercraft could be assimilated by the girls in elementary schools, while Miss M. DOUGLAS WILSON (health visitor, Derbyshire C C.) thought that to begin with the mother was to begin too late, as many superstitions had to be cast out of their minds

Abuses of laundry work.—Mdlle. DOROTHEE ROBERT (secretary of the Union of Belgian Laundry Women) called attention to the disadvantages under which laundry girls and women worked in Belgium.

Young girls of 14 or 15 years had to carry heavy baskets of soiled linen or wheel a heavy hand cart, if no one under the age of 18 were allowed to do this work the proprietor would hire a lorry, as the time of adults is too precious to be wasted in fetching and carrying the washing Soda was used in excessive quantities to replace the dearer soap, and in winter chlorine to bleach the linen, both these practices affected the skin of the hands and gave rise to sores Mdlle Robert said she had known women at special times iron for 102 hours a week Out of 50 or 60 women she had known during the 12 years she had worked in a laundry only five had not had varicose veins at the age of 16 or 17 She appealed for more visits by inspectors at night as well as by day, and for improvement of ventilation, drainage, hours and conditions of work in laundries, and for a room set apart for the workers meals

Dr. CHRISTINE MURRELL gave an account of the growth of a child welfare centre. In order to avoid encroaching more than necessary on the scanty leisure of the hardest of all workers, the home keeping mother, treatment, including dental treatment, should be provided *at* the centre.

Dr. S G. MOORE described the system for the voluntary notification of pregnancy introduced by him in 1916 in Huddersfield The system had worked without difficulty or complication of any kind The percentage of notifications had gradually increased from 11 to 34. The visits to the mother were made by a medical woman; if any condition were found requiring treatment the expectant mother was advised to consult her usual doctor, a copy of the report was sent to the doctor and midwife. A following up visit was made after a short interval. Great importance was attached to doing or saying nothing which might reflect in any way, however remotely, on the prestige of a midwife. Material help was also afforded, home helps were provided if necessary.

Dr ERIC PRITCHARD spoke against the separation from its mother of the young infant sent to hospital Certain abdominal operations performed in hospital were very dangerous, although successful when carried out in the home, he attributed these results to infection, since the baby was immune to the germs in the environment of its own mother, but not to foreign germs.

At the final meeting of the section several resolutions were carried which, if officially adopted, will assist in bringing the Belgian social legislation up to the level of the British.

Industrial Hygiene.

The Section on Industrial Hygiene discussed the necessity for providing more adequate first aid equipment in accordance with the special needs of various factories, and of their periodical inspection by doctors It was agreed that the hygienic conditions of factories are not sufficiently controlled, there are only three medical inspectors of factories for the whole of the United Kingdom. Although the lay inspector could check the number of washing basins, w c 's, and urinals provided they naturally consider that this is not part of their job, and the result is that the w c.'s especially are too often left in a most objectionable condition. Many speakers considered that ventilation and lighting require further control, but that the methods of testing lighting now recommended are too laborious It was suggested that much the same practical tests should be applied to the lighting of factories as those used in testing the adequacy of lighting of forecastles of ships. If when the lighting is reduced by one third a newspaper can be read in any part of the forecastle the lighting is considered to be adequate. Similarly, a workman should be able to read a newspaper placed in the position of his work in any part of the workshop, and this practical test was generally regarded as sufficient.

Miss A M. ANDERSON (Principal Lady Inspector of Factories) stated that successful production depended on skilled attention being paid to the personal health and welfare of the worker.

During the war, with its call for speed in the production of munitions, it was possible to make a rapid advance in the provision of industrial canteens, first-aid, rest-rooms, cloak-rooms, washing conveniences, and improved selection of workers for particular processes, and in various ways to advise recreation to prevent excessive fatigue and to restore the over-tired worker. She said that the knowledge gained of useful measures for promoting welfare was being rapidly spread and popularised by official pamphlets from the Home Office, and orders under the Welfare Clause of the Factory Act of 1896 were steadily increasing the local requirements in this direction. It was to be hoped that the governing body of the International Labour Offices when preparing the agenda for the Annual Labour Conference would receive many suggestions from employers and workers in well-run factories.

Mr. H. J. WILSON (H.M. Superintending Inspector of Factories, Scotland), read a paper on the Employment and Distribution of Industries in their Relation to the Physical Development of the Young Workers. The work of the National Service Medical Boards, 1917–18, demonstrated the unsatisfactory physique of recruits from the textile districts. He quoted the following figures:—

	Height.			Weight.	
	ft.	in.		st.	lb.
Men born and bred in rural areas (440 examined)	5	8·8	......	12	4
(Sheffield) City-bred indoor worker (1080 ,,)	5	4·35	......	9	10
(Birmingham) ,, ,, ,, (500 ,,)	5	6·6	......	9	8
(Glasgow) ,, ,, ,, (230 ,,)	5	2	......	8	12

But it would seem that the occupation in itself is not always at fault; in the jute industry round about Dundee the physique of the workers in the country factories was much superior to those of the town. It was suggested that the rain and inclement weather of the northern towns prevents the young city children from getting out into the open air as much as in the drier cities of the south.

A practical paper was read on Miners' Nystagmus by Dr. T. LISTER LLEWELLYN. The general view of the section was that nystagmus was caused by defective lighting, although one speaker still considered that the cramped position was at fault. Dr. Llewellyn held that the underground ways in mines should be whitewashed or the walls should be sprayed with moistened non-siliceous stone dust. Optical glare must be avoided, and the light should be thrown on to the miner's work by an electric lamp supplied by an accumulator, the light being fixed on to the man's head or chest according to the actual working position assumed.

Mr. LEON GASTER (honorary secretary of the Illuminating Engineering Society) said that adequate industrial lighting, avoiding glare and eliminating inconvenient shadows, would lessen accidents, fatigue, and increase output. The interim report issued in 1915 by the committee appointed by the Home Secretary recommended that there should be general statutory power to demand adequate lighting in factories. Tests recently conducted in the United States of America showed that when industrial lighting was improved a very considerable increase in output (8 per cent. to 27 per cent.) had resulted. A slight gain in efficiency would amply compensate for the increased expenditure in lighting. In America six States possessed legislative codes of industrial lighting. International action was necessary, so that all countries would adopt the same general principles in framing their regulations.

Naval, Military, Tropical, and Colonial Hygiene.

This section was well attended by French and Belgian service medical officers. M. VINCENT expressed his belief in the value of the prophylactic treatment of dysentery by antiserum injections.—Major JAMOT gave his experiences of the organisation of a prophylaxis section against sleeping sickness and its results in French Central Africa. It was advisable to avoid establishing settlements in the tsetse fly zone, but when these were absolutely necessary the bush and low undergrowth should be cleared. Early diagnosis before the disease had obtained a grip of the patient was as important as in syphilis.—Dr. G. C. LOW advocated the intravenous injection of antimony tartrate for bilharziasis and gave a detailed description of the technique and dosage.—Surgeon-Captain P. W. BASSETT-SMITH (chairman of the section) spoke of anthrax from Japanese shaving-brushes, and referred also to the antiscorbutic potency of lozenges made from concentrated lemon-juice.

Bacteriology.

Professor J. G. ADAMI in his opening address as President of the section emphasised the urgent need for placing the classification of species and variants upon a rational basis in view of the confused jumble in nomenclature and in differential methods which the intensive research of recent years had produced. He urged the formation of a committee to attain this most desirable end on international lines.

Perhaps the most interesting feature of the section was the discussion on milk. A valuable paper on some aspects of the milk problem was contributed by Dr. R. STENHOUSE WILLIAMS (Research Bacteriologist for the Board of Agriculture), who is working at Reading in conjunction with Captain J. Golding.

The author gave the results of the bacteriological examinations of 27 samples of milk supplied to different welfare centres. The bacterial counts were high; dirt was found in all the samples, two of which also contained the bacillus of tuberculosis. The unsatisfactory condition of the milk had led welfare centres to adopt different milk products rather than whole milk for the feeding of infants. The diminution in the consumption reacted upon the milk industry, so that the sales were relatively low and the price in the past had been unsatisfactory. In addition the industry was put to serious monetary loss as the result of souring, splashing of milk from the milk churns, unequal supplies from milk producers, and the need for pasteurisation.

An inquiry into the causes which led up to these conditions showed that in the past the consumer had been quite unwilling to pay more than a flat rate] for milk. The farmer had not known what it cost him to produce his milk and had not kept milk records, so that he did not know which of his cows were profitable and which not. The dairy schools in the past did not teach methods of clean milk production, with the result that the dairy farmer had no real conception of the work he was undertaking. The milk was put in churns which had never been properly cleansed either by the receiver of the milk or by the farmer; they travelled by rail under unsatisfactory conditions, to be handled on a railway platform under conditions which were still more unsatisfactory, and were finally delivered to the consumer after suffering much at the hands of many different persons, amongst whom there was an entire lack of coöperation. Indeed, in many cases the trade interests of the people concerned in the production and distribution of milk were diametrically opposed.

An improvement of the milk-supply in this country might take place during the next generation, for the consumer was discovering the value of fresh milk as a food, and the control instituted during the war had established the right to charge a better price for a better article; further, the investigations of the Costings Committee, the insistence upon income-tax returns from farmers, and the increased cost of foodstuffs and labour had caused farmers to study their cost of production more carefully. Attempts had also been made to bring producers and distributors into mutual coöperation. The ultimate success of the movement would depend upon the consumers' appreciation of milk as a food and upon their willingness to pay a reasonable price for an improved article.

Professor J. SHARE JONES (Liverpool University) put in a plea for the better education of veterinary students. Not so much the clinical work of veterinary surgeons, but their scientific knowledge might be greatly increased. The improved scientific education of the veterinary surgeon would result in his being used more for preventive work; the problem of clean milk would then be rapidly solved by his real influence on the farmer.—M. M. KUFFERATH, who is working at the Chemical Laboratory in Brussels and the Pasteur Institute, read a useful paper on the Systematic Examination of Milk. His scheme is very much the same as that used in America. On a single sheet he gives information as to the bacteriological content, the presence of *Bacillus coli* and tubercle bacillus, the presence and number of leucocytes, and the quantity of filth. Marks are given to the milk under each heading, and a report is sent on to the town hall to the administrative department for action if necessary. He described a recent epidemic of gastro-intestinal disease arising from pathogenic streptococci in milk, derived from one cow affected with mastitis out of a herd of about 40. Organisms were present in only a limited proportion in the milk, but 135 persons were affected and a number of children died.—Dr. R. M. BUCHANAN (the city bacteriologist of Glasgow) stated that a similar outbreak had taken place in that city, but had not affected the gastro-intestinal tracts so much as the pharyngeal and tonsillar regions.—M. KUFFERATH found that the long streptococci in the last stages of disease in the cow became shortened to resemble *Streptococci pyogenes.*

The general feeling of the meeting with regard to milk was that the milk shed should be made almost as clean bacteriologically as an operating theatre, and that antiseptics would probably be of more avail than an attempt at asepsis.

Anaerobes —A discussion on Anaerobes was opened by Professor WEINBERG (Pasteur Institute, Paris)

His communication dealt with the serum treatment of gas gangrene as being the latest phase of his already distinguished work on the bacteriology and experimental pathology of this extremely varied infection Indisputable proof was given of the value of antitoxic sera in the great majority of cases it was notable that the serum injections were not attended with ill effects in those who had received tetanus antitoxin in connexion with a previous wound The success already gained by Professor Weinberg gives promise of complete mastery over this polymicrobic complication of soil contaminated wounds In the latter part of his paper he discussed the value of complement fixation in identifying the multiplicity of microbes in an affection such as gas gangrene and emphasised the necessity of keeping in view the possibility of group reactions

Dr BUCHANAN contributed his experience of finding a number of the types of anaerobic bacilli in the course of a large series of hair dust examinations, primarily undertaken for the discovery of the bacillus of anthrax

The morbid lesions resulting from many of the experimental inoculations of the hair dust were similar to those of gas gangrene and the organisms found were of the same types In 225 subcutaneous inoculations there was a mortality of 18 per cent due to anaerobes alone and another 10 per cent to their pathogenic action in association with the bacillus of anthrax The hair of animals was naturally exposed to contamination by soil and excrement and the resulting hair dust was therefore liable to harbour the spores of anaerobes similar to those associated with the gangrene occurring in war wounds He mentioned that most of the shaving brushes responsible for the spread of anthrax were imported from Japan with the certificate that they had been disinfected The British authorities however were instituting disinfecting stations throughout the country for materials of this character

Dr DAVID THOMSON made an interesting contribution towards our knowledge of biochemical organisms

He has succeeded in growing masses of gonococci reaching the bulk of 50 c mm (about the size of two thumbs) He has split the germs biochemically into three substances soluble in alkali in acids and alcohol respectively All organisms contain these three substances in different proportions it is now possible to identify germs biochemically according to the proportions present For instance gonococci contain 90 per cent acid soluble and 10 per cent alcohol soluble substances tubercle bacillus contains 40 per cent alkaline soluble 30 per cent acid soluble and 30 per cent alcohol soluble substances Toxin can be separated from all three of these substances Later he found that the different toxic remainders are antigenic as estimated by the complement-fixation test being comparatively non toxic considerable doses can be given—namely up to 10 000 million or more All animal flesh can be split up into the same three substances as organisms and a material apparently identical with the toxin from bacilli has been obtained from all the various proteins of animal and vegetable origin he has examined All living things apparently contain some endotoxic product This material is secreted in the urine Other interesting bio-chemical substances obtained from bacilli are various indicators such as tumeric these are also found in the urine

Dr COHEN read a paper on a Diplococcus found in a Case of Acute Articular Rheumatism which, while allied to the gonococcus, did not respond serologically to that organism He held the view that acute rheumatism was a disease that in one patient might be caused by one organism, and in another by a different organism

Dr W E GYE and Dr W CRAMER communicated a note of their work on the rupture defence mechanism in connexion with the anaerobic micro organisms of gas gangrene

Professor BENJAMIN MOORE advocated the use of nitrogen peroxide for disinfection of the upper air passage in influenza and other respiratory diseases

Chemistry

Water supplies —On the first day a group of papers dealing with water supplies was read, they contained a summary of the experiences of the sanitary medical officers on the various fronts and of water engineers of towns The discussion centred on the chlorination of water supplies It was considered that this method had been proved the best for purifying water in the field in Gallipoli and France and on other fronts The slightly objectionable taste sometimes found was accounted due to chlorination being imperfectly carried out unfortunately excess could only be removed by methods impracticable for the field The Horrocks s box must be used and the correct amount of bleaching powder added It was agreed that the R A M C soldier belonging to the Sanitary Section and the man in charge of the water carts, usually an ordinary private, should be instructed in principles of chlorination of water In the Belgian army the Horrocks s box was apparently not used —Mr JOSEPH RACE (the water engineer of Hereford) communicated an exceptionally valuable paper on the Chlorination of Town Water supplies

The ability of medical research to save money was demonstrated by Professor BENJAMIN MOORE, the President of the Section his investigations on the path of entry of trinitrotoluene into the human system saved the nation a very considerable sum He found it unnecessary for the workers to wear respirators, as the substance was not absorbed through the lungs Certain susceptible persons by rolling the product in their hands, get it into their systems

Accessory food factors —On Friday afternoon a discussion took place on Accessory Food Factors The most controversial paper was read by Mr JEPHCOTT, M Sc , who said he had demonstrated that although the antiscorbutic vitamine is the most susceptible to the influence of heat, it is not destroyed during the drying of milk by the roller process This was opposed to the view of the workers at the Lister Institute, who consider that a certain amount of destruction takes place Mr Jephcott held that their conclusion resulted from the difficulty in feeding guinea pigs with milk, they cannot take a large amount, but he fed the animals with milk in double concentration and found no disease occurred —Mr J E DRUMMOND, D Sc (member of the Joint Medical and Lister Institute Committee on Vitamines), gave an account of the work of this committee —The paper of Dr E ZUNZ (University of Brussels) was a valuable contribution to the study of vitamines

Captain GOLDING S paper showed the need of research in the bio chemistry of milk production

He held that milk was a perfect food for mammals of the same species if the mammals who produced the milk were living under natural conditions When the cows were housed in shelters and fed artificially vitamines might be deficient in the milk We did not know the extent to which vitamines were deficient in winter milk research was being carried out on this point at the Dairy Research Institute University College Reading The paper on the Contamination of Milk brought out the point that lactic acid organisms were not harmful in themselves as was well known in Ireland many of the peasants never drink milk in its fresh state but always when sour In the East milk was put into animal skins with the express purpose of souring it In ordinary town supplies however the souring of milk was an indication of the presence not only of lactic acid organisms but also of those associated with the presence of manure in the milk

A General Resolution

A recommendation was sent by the section to the Council of the Institute that a general resolution should be put forward pointing out the necessity of practical instruction of the public in the elementary laws of hygiene and nutrition and the prevention of disease. It was universally agreed that this International Conference could not fail to have good results

TUBERCULOSIS

"Natsopa ' and the Psychology of Industrial Convalescence

'NATSOPA is a Lewis Carroll name for the new tuberculosis sanatorium of the National Society of Operative Printers and Assistants This institution is an outcome of close and friendly cooperation between employers and employed associated in an effort to remove from the printing industry the stigma of consumption It is an instance of a trade voluntarily shouldering its own responsibility for the health of those who follow it, and so a duty owed to the community is fulfilled The sanatorium, which is situated at Wellsborough Leicestershire and was recently opened by Lord Northcliffe is managed entirely by operatives and owes its being to the keenness of Mr G A Isaacs general secretary of the society The line of treatment has already been tried with success in America for this is not an ordinary sanatorium It is a factory as well and the convalescing patient is to be encouraged to work for such period as he is medically allowed *at his own trade* The psychological effect upon a convalescing patient of getting back to skilled remunerative employment and not wasting his time doing nothing, or attempting too early to resume full working hours, to be followed by early relapse, can hardly be over estimated There can be little doubt that ordinary sanatorium treatment has owed its partial failure to lack of after-care on these lines. The principle of after-care to be followed is that strongly recommended in the first report issued by the Medical Research Committee early in 1915; and although this report dealt with the boot and shoe industry, the recommendations apply equally to the printing trade, and were brought to its notice.

The psychology of industrial convalescence is here fully recognised from two points of view. First, with regard to the influence exerted by occupation instead of idleness, and then by that occupation being useful and of the kind which is to be followed when full health is regained. What is of accepted value for the convalescing consumptive is equally of value for other forms of disease—a fact which is now being recognised by the Ministry of Pensions for invalided soldiers. Useful occupation, whether it takes the form of training the disabled in order to convert them into productive members of the community instead of leaving them to be dependents on charity, or of resuming by easy stages a skilled process, facilitates recovery and converts a discontented invalid into an eager craftsman. We must no longer be content to free patients from the acute period of disease, but must conduct them through practical convalescence to resume their place in life as productive units.

Vejlefjord Sanatorium Publications.

The annual report (1919) for Vejlefjord Sanatorium, Denmark, marks the twenty-fifth anniversary of the sanatorium. There are two clinical papers, one by Professor Saugman on pneumothorax treatment, the other by his assistant, Dr. Gravesen, on the treatment of tuberculous pleural effusions. Professor Saugman also contributes "A Retrospect"—a survey of the achievements of the antituberculosis campaign in Denmark since the middle of last century. But the most valuable of all the papers in this report is undoubtedly Professor Saugman's analysis, made in 1920, of the cases discharged in the period 1900–17. Of the 2360 patients in this category, all but 164, or 6·9 per cent., were traced. By 1920, 44·9 per cent. of the total were fit for ordinary or light work and 42·5 per cent. had died of tuberculosis. There were also 65 deaths from causes other than tuberculosis. It was found on analysis of this material, according to the various stages of the disease, that 78·6 per cent. of the first stage cases, 73·6 per cent. of the second stage cases, and 27 per cent. of the third stage cases were fit for ordinary or light work in January, 1920. The deaths from tuberculosis in these three stages were 5, 15·2, and 61·7 per cent. respectively. In connexion with these remarkably good results it should be borne in mind that Vejlefjord Sanatorium caters for the upper and middle classes.

Tuberculosis Journals.

The April number of the *American Review of Tuberculosis* (Baltimore: National Association for the Study and Prevention of Tuberculosis. 35 cents.) begins with a paper by Dr. J. Burns Amberson and Dr. Andrew Peters on the effect of influenza on pulmonary tuberculosis. Their investigations into the fate of 1544 ex-patients from Loomis Sanatorium show that of 86 deaths 18·6 per cent. were due to influenza. Of the patients admitted to the sanatorium during 1919, 21 per cent. had suffered from a definite attack of influenza during the recent pandemic. After reviewing the extensive literature of this subject, they conclude that no convincing evidence has been produced showing that tuberculous individuals possess any immunity to influenza. They also find that influenza often marks the inception of definite pulmonary tuberculosis which did not previously exist as a clinically demonstrable disease. In a short note on ten cases of pulmonary tuberculosis treated with sodium gynocardate "A" Dr. Max Biesenthal finds this drug valueless. A paper by Dr. John N. Hayes on Secondary Invaders of Tuberculous Lungs emphasises the sinister importance of *Streptococcus hæmolyticus* in connexion with cavity formation. In a paper freely illustrated by tables, Dr. Edgar Mayer describes his experimental studies on the Effect of Ultra-violet Light on the Intradermic Tuberculin Reaction. In a paper on Work Classification for Sanatorium Patients Dr. William T. Cannon unconsciously gives the key to the problem of sanatorium unrest in institutions where consumptive labour is exploited. He writes: "The advantage the sanatorium derives from its patient employees is one of economy, as it is enabled to avail itself of labour at very much less cost than if regular city employees were used, thus reducing the running expenses by thousands of dollars a year." The last, but one of the most interesting, of the original papers is by Dr. S. Adolphus Knoff, an old pupil of Dettweiler. Discussing Ideals in the Treatment of Tuberculosis, he indulges in digressions as instructive as his main theme. One of his digressions is an eloquent refutation of Professor Fishberg's libel on the consumptive, whom he has stamped as selfish, egotistical, and egocentric. Dr. Knoff's long list of unselfish consumptives includes the name of Captain Georges Guynemier, who fought 800 battles in the air and brought down 74 enemy aeroplanes, becoming the famous ace of aces before his death in action over the German lines.

Pensions for Consumptive Soldiers and Sailors.

The Minister of Pensions announces that, having considered the recommendations of the Inter-Departmental Committee on Tuberculosis (Sanatoria for Soldiers and Sailors) 1919, he has decided that men suffering from pulmonary tuberculosis attributable to or aggravated by service, who on the conclusion of sanatorium treatment undergo a prescribed course of extended treatment combined with training in a training colony, shall be granted a pension at the 100 per cent. rate for six months from the date of leaving the colony. Thereafter they are to receive a pension at the rate corresponding to the degree of their disablement, but not less than 50 per cent., throughout the subsequent period of two years. This award will be subject to the condition that the pensioner presents himself when required for inspection and consideration as to the need for further treatment. The arrangement will apply also to the pensioner who is not recommended for a further course in a training colony, the 100 per cent. pension in his case commencing from the date of his discharge from the sanatorium.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Report of the Irish Public Health Council.

THE Report of the Irish Public Health Council, which has been expected for some time, was laid on the table of the House a few days ago. Until the entire document has been studied one cannot give a considered opinion on the many points raised in the Report. There are, however, some outstanding features to which I may be permitted to draw attention without delay. Perhaps the most noticeable fact in relation to the Report is that, with the exception of one paragraph, it is unanimous. It is true that the exception, dealing as it does with the constitution of the central authority, is not altogether unimportant, but, nevertheless, it is noteworthy that a Council, consisting, apparently, of very discordant elements, should in a few months have agreed on so many suggestions of a far-reaching and radical nature as the Report contains. The suggestions put forward will no doubt receive and benefit by many criticisms, but it must be admitted that the scheme as a whole is courageous, and further that it contains much of what has been steadily demanded by the profession for years back. The Council suggests the establishment, for example, of a Ministry of Health for Ireland, with its more important activities under the control of a representative and democratic council; the establishment of an Irish medical service, with entry by competitive examination; the total separation of medical work from the Poor-laws; and the development of sanitary administration in Ireland. On all these points the Council has gone far to meet the demands put forward by the profession

No doubt the Report is not all the profession would like it to be, for a necessary condition of unanimity is compromise The great weakness of the whole scheme is to be found in the fact that the Ministry of Health proposed to be established is—as in England—to have many functions unrelated to health The Council states that it made every endeavour to find another solution, but failed One may surmise that some of the difficulties were as much personal as intrinsic It is a pity that a Ministry which should find its energies thoroughly occupied with matters directly bearing on health may have to fritter away its time on the multifarious activities The introduction into the very heart of the Ministry of a council with power of control and not merely of advice, is something of an experiment in Irish administration which one heartily welcomes It is true that there is an excellent precedent in the Congested Districts Board, where the entire Board, except two members, is chosen as representative of the interests with which the Board deals Of the proposal to establish an Irish medical service with direct entry by competitive examination, with immediate absorption of the entire Poor law medical service as we know it, we do not anticipate any serious criticism from medical quarters, or, indeed, from educated lay opinion Where medical criticism will chiefly be heard will be in regard to the duties to be entrusted to the medical service It is proposed that it should give attendance not only to the poor but to insured persons Unless this intention is worked out with great care it will cause serious disturbance to many medical men engaged in working class practice The Council has realised that such a difficulty exists, and states that rigid lines cannot be laid down at present, and that it may even be necessary to exclude certain industrial areas from the general scheme Again, medical criticism will no doubt, object to the inclusion of all insured persons in the class to whom the medical service is to administer, and will demand an income limit In a first impression of the Report I only mention one other point at present—the attempt to link up the entire hospital system and connect it with the domiciliary curative work, and at the same time to help to solve the problem of the voluntary hospital This seems to be on all fours with the Interim Report of Lord Dawson's Consultative Council

The Tragic Death of Dr Frederick Charles Smyth

Gloom has been cast over the medical profession in Belfast by the sudden death of Dr Frederick Smyth from a motor accident, which occurred shortly after midnight in Ashley avenue, a few yards from his own residence At the inquest the jury returned a verdict of "Death from shock and laceration of the brain following fracture of the base of the skull accidentally received by being knocked down by a motor car while assisting to start it" The jury expressed sympathy with the widow and family of the deceased, and commended both to the consideration of the gentleman who was driving Dr Smyth, and who promised that he would do all he could in the direction indicated

Queen's University of Belfast

In connexion with a new department of dentistry the Senate of the Queen s University of Belfast, at a meeting on June 16th, made the following appointments lecturer in dental mechanics Mr H Elwood, L D S, lecturer in dental surgery, Mr W Marshall Swan, L D S, lecturer in orthodontia, Mr H T A M'Keag, B D S, lecturer in materia medica and metallurgy, Mr W H Hunter, L D S The Belfast hospitals are taking steps to provide the necessary clinical facilities The Senate also appointed a committee to consider the whole question of the establishment of a department of veterinary science, as requested by a deputation of Belfast veterinary surgeons, who, as representing the North of Ireland Veterinary Medical Surgeons' Association, had appeared before the Standing Committee of the University

June 21st

PARIS

(FROM OUR OWN CORRESPONDENT)

The Budget of the Ministry of Hygiene

THE budget of the new Ministry—de l Hygiène de l Assistance, et de la Prevoyance Sociale—is at the moment under consideration by Parliament The total demand is for 242 million francs, of this sum 105 millions are to be devoted to purposes of relief and only two and a half millions to hygiene This figure is universally considered too small, in view of the enormous efforts that must be made in the prophylaxis of infective diseases alone The Academy of Medicine, on the motion of M Roux, director of the Pasteur Institute, has made a vigorous protest, demanding an increased vote of credit In the House the estimate of 300 000 francs for tuberculosis dispensaries was immediately raised to three millions

New Hospitals for Paris

The plans of reconstruction of the Paris hospitals already outlined in THE LANCET have been developing on more definite lines M Mesureur, the Director of the Assistance Publique, has asked for a vote of 150 millions, the expenditure of which would be spread over 10 years involving an annual addition of 15 millions to the income of the town of Paris The Hôpital Beaujon and the Hopital de la Charite, in the centre of Paris both old buildings which are tumbling down, will be demolished and reconstructed outside the actual radius of the capital each on a site of 100,000 square metres with modern equipment, maternity and tuberculosis departments, and so forth A second lying in department will be constructed at the Maternité at a cost of 640 000 francs The surgical department of Professor Gosset at Salpetriere will be rebuilt and greatly enlarged, the cost will be 1,100,000 francs, of which Professor Gosset himself will give 350,000 for the installation of an amphitheatre and class rooms At the Hopital Necker Professor Legueu's department will also be enlarged, and of the estimated cost of 680,000 francs Professor Legueu offers 50,000 His predecessor, Professor Guyon, in his time also contributed to the equipment of his department At the St Louis, St Antoine, Laennec, Enfants Malades, and Enfants Assistés hospitals extensions are being contemplated, and new maternity and physio therapeutic departments, and special departments for radium therapy, will be erected The Hopital Claude Bernard for epidemic diseases will be extended to double its present size, the Hopital Bichat will be transformed and enlarged, the Hopital Cochin will also be enlarged and extended, and will take over the old hospital for male venereal diseases (Hopital Ricord), a third pavilion will be built to the new Hôpital de la Pitié, to be devoted entirely to tuberculous patients The naval hospital at Berck sur mer, which belongs to the Assistance Publique of Paris, will be enlarged and protected against encroachment by the sea by large works (140,000 francs), a sanatorium with 1000 beds for curable consumptives will be built in the department of Seine et Oise, at Thins The municipal council of Paris has decided to raise the daily fee payable to the hospital by patients who are not paupers because of increased expenses, from 5 francs to 17 20 francs in the medical wards, and from 10 to 19 francs in the surgical wards

The Hygiene of School Buildings

For some time prefects have been in the habit of lending school buildings during those hours when no classes are being held, especially on Sundays and in the evenings to various societies for scientific congresses, musical or social gatherings and during election times political meetings Of late these meetings have become so numerous in some districts that the proper cleaning and disinfection of the building has been seriously impeded, and the council of hygiene of the department of the Seine has issued an order asking the prefects in the interests of school hygiene to refuse to authorise the use of school buildings for any outside purpose

"Audi alteram partem."

THE OUTLOOK IN DENTISTRY.

To the Editor of THE LANCET.

SIR,—In your leading article of June 5th on the outlook in medicine and dentistry it is stated that "Even if they devoted their whole time to school work the existing dentists could not cope with the needs of the 5,750,000 school children while neglecting the rest of the population." Instead of the figure given, evidently elementary school children, let us take the number of children in England and Wales alone between 4 and 14 years of age, roughly 7,000,000, almost one-fifth of the entire population; and suppose we have started clinics with all our 5000 dentists full-time, having obtained the consent of all the parents to full treatment; deduct 3 per cent.—i.e., 210,000—as having naturally perfect teeth, leaving 6,790,000 to be treated, which gives 1358 children to each dentist, or, after allowing for administration and inspection, 1500 each. As there would neither be part treatment nor casual cases, this number could, without undue fatigue, be made dentally perfect—that is, every saveable tooth filled or otherwise treated, and every unsaveable tooth removed within one year, after which 700 dentists, or one to every 10,000 children, could keep them in that state, inclusive of treating those entering each year; while the remaining 4300 dentists could tackle the children of Scotland and Ireland and then the adults of the United Kingdom in sections of 10 years of age, leaving behind in each section one dentist to each 10,000, or for the 46,000,000 in the United Kingdom 4600 dentists. This is the ideal.

The real is, that if we appointed 5000 dentists for this purpose 4300 would have to "kick their heels," excepting only those in areas in which a dental clinic has been in existence for some years, where this system might be tried with advantage, forming training schools for those entering the school service, thus giving six months to a year of intensive training, which could not be got elsewhere, before taking charge of a clinic, at present some are started on wrong methods, which require subsequent strenuous labour to right, such training would obviate this. Where no dental clinic exists the great majority of the parents object to dental treatment for their children, except for the relief of pain, and, anything in the nature of compulsion, until the great majority are converted, would lead to active antagonism.

At the present time not more than 1000 dentists, inclusive of inspectors and teachers, could find sufficient work to keep themselves busy, and that number would be ample to eradicate dental disease to the extent of 90 per cent. or so within the next ten years; but these men must be not only qualified but must be men of experience in the first instance, capable of giving sound training to younger men, and the work must be of the best and most enduring quality, so as to reduce to a minimum the need for subsequent treatment throughout the child's life, otherwise the whole system will be a fiasco. Needless to say, a sufficient number of such men cannot be got for anything like £350 or £400, so often offered; but, given prospects equal to what obtains in other lines of life, a plentiful supply is at hand, which would be readily augmented by the time that a full system could be inaugurated, once it were known that the remuneration would be in proportion to the expense and study involved.

In your report of the President's address to the General Medical Council (p. 1235) the increased number of dental students in 1919—viz., 612—is given as a hopeful sign; during the years 1912–15 inclusive 1208 were registered, for the years 1916–19 inclusive 1074, a considerable fall, indicating also that the number for 1919 is mainly made up of some of those who delayed their course on account of the war, while it also includes assisted ex-service men. No parent knowing the facts will dream of wasting his money, or his son's brain-power, in such a line, unless he has sufficient capital to enable him to cater only for the wealthy—a class of man we do not desire to enter the profession, otherwise the prospects in private practice for the young man are well-nigh hopeless, "tied hand and foot," wearily waiting for merit to tell, while the unskilled canvass and advertise all around him, using titles indistinguishable from, but often more high sounding than, his, an unjust competition which does not affect the long-established man to any great extent. The scarcity is not yet really serious, but is accentuated by faulty distribution, want of organisation, the wastage of skilled energy in the production of beautiful, though often unnecessary and vulgarly placed, specimens of the goldsmith's art, and time lost in ultra-conservative treatment, where radical treatment would in many cases prove to be the more conservative in the long run. If 44,522 medical men are sufficient, after allowing for faulty distribution, for the rest of the body, surely 5455 dentists are not far short of what should be required for the teeth alone.

This scarcity of dentists scare is being pushed for all it is worth by those who wish to be put on the Register, "with all the legal rights, privileges, and status, as are conferred by the Dentists Act, 1878, upon dentists," because they find that the competition of the steadily increasing number of persons practising like themselves, to which is added the steady awakening of the public to the difference between a dental surgeon and the keeper of a "dental surgery," is becoming too great. They hope to get the status, &c., that the Government will join with them in this fraud on the public, and once safely in, to slam the door upon anyone who cannot prove himself to have been for five years at least "an uneducated, untrained person, practising as a dentist, performing surgical operations on the teeth and jaws, doing untold damage and casting undeserved odium and dishonour on a scientific profession"—vide report on the Dentists Act. I blush for the members of our profession who agree to have them on our Register, as medical men would had any of their members proposed to put all the venereal and other quacks on their Register, on the strength of vested interests. It is a most vicious precedent.

As a school dentist I trust that something will speedily be done to protect those children now leaving school with perfectly healthy mouths, mainly due to clinic treatment, from such men, many of whom are utterly unscrupulous, one of their favourite tricks being to advise wholesale extractions for tartar-coated teeth.

I am, Sir, yours faithfully,
A. SHERWOOD ANDERSON,
Northampton, June 15th, 1920. *School Dental Officer.*

RESEARCHES ON THE TREATMENT OF BENIGN TERTIAN FEVER.

To the Editor of THE LANCET.

SIR,—I read with the greatest possible interest and with considerable profit the valuable contribution of Major H. W. Acton, I.M.S., on this subject published in your issue of June 12th. It contains much solid and practically useful information regarding the alkaloids of the cinchona plant. Indeed, one looks upon this paper and another issued by Major P. M. Rennie, I.M.S., both records of the work done in the Dagshai Malaria Depôt for British Troops, as among the most useful documents on the treatment of malarial fevers by quinine and its alkaloids that have been published. Having had something to do with the establishment of the malaria depôt at Dagshai I watched the work carried on in it with exceptional interest. I am in a position to vouch for the accuracy of the details of the work of the first series of cases published by Major Rennie, and am also satisfied that those of the second series now under reference are *pro tanto* absolutely reliable. Major Acton's work was on similar lines to the admirably worked out and complete series of observations made by Professor J. W. W. Stephens and his collaborators and published in the *Annals of Tropical Medicine and Parasitology*, 1919.

There are a few points in Major Acton's paper with which I do not find myself altogether in agreement, and to which, with your permission, I will take the liberty of alluding. Major Acton has admitted that some of his *opinions are opposed to long standing beliefs regarding the effects of quinine in malarial infection in India*

1 His recent work leads him to conclude that the malignant tertian parasite is more amenable to complete eradication under the curative use of the salts of the quinine alkaloid of cinchona bark than the benign tertian parasite The reverse has been the opinion always held in India In his paper he admits that he only dealt with 15 cases of malignant tertian infection, and I know from my own notes that there was only one case of malignant tertian infection in the first series—that is, Major Rennie's—which dealt with the Dagshai cases up to Sept 30th, 1918 I do not include the diagnoses made regarding the cases on the plains anterior to their being sent to Dagshai, as I am of opinion that these latter diagnoses should not be included by Major Acton, who, I take the liberty of remarking, would be on safer ground if his deductions were based on observations actually made by himself and his colleagues *If this view is accepted then one is disposed to consider that the number of malignant tertian infections dealt with by him and his collaborators is scarcely sufficient to justify a definite conclusion as to the relative curability of this type of malaria by quinine as compared with the effects of quinine in benign tertian infection* I would suggest that a much more extensive series of observations of the same kind on malignant tertian infection are necessary before arriving at any positive conclusions as to its curability compared with other types of malaria by quinine salts I fully admit that Major Acton has made out a strong case in support of his statement that quinine acts as a steriliser of the blood in connexion with *Laverania malariæ* infection—that it has a more decidedly specific action on this parasite than on the other two, and he has brought forward a series of facts not easy to refute

2 My own experience in India and Burma, which goes over 28 years and includes something in the neighbourhood of 200,000 cases of malarial infection, indicates that benign tertian infection forms probably over 75 per cent of the malarial infections met with, and not 50 per cent, as stated by Major Acton My observations were carried out almost all over India This is the general average for an entire year The ratio of benign tertian and malignant tertian infections in many parts of India varies with the period of the year, the percentage of malignant increasing and that of benign tertian decreasing during the autumn This is specially brought out in the malaria of our extensive N W F Provinces I do not believe this difference to be due to raised atmospheric temperature, as appears to be the case in temperate climates, it is I submit, owing to some undiscovered *factor in connexion* with the life history of malaria bearing *anopheles One has investigated malaria at all periods of the year in India, Burma, and Mesopotamia,* and knows that it is *necessary to continue observations for* a whole year before anything like a true *record of the ratios* as to the types of malarial infection is to be obtained for each locality, district, or cantonment

3 The difficulty of completely eradicating *Plasmodium vivax* from the blood appears to be proved by the work done in the Dagshai Malaria Depôt, this was also well brought out by Professor J W W Stephens and his co workers during the great war, and should cause many to revise their opinion as to the innocence of this type of malarial infection I have long been of opinion that benign tertian malaria is a much more important type of infection in India, both as regards direct and indirect mortality and the extent of morbidity it gives rise to, than malignant tertian infection One published many statements to this effect years ago The following is abstracted from "Prevention of Malaria in India," 1911, p 100 —

> The vast majority of the cases of malaria in India consists of simple tertian which is considered by most authorities to be the easiest *form* of malarial infection to eradicate *from a* locality and from infected *persons This does not correspond altogether* with the experience of many experts in India Notwithstanding statements to the contrary the largest number of relapses occurs in cases of simple tertian fever During the last ten years one has had opportunities of watching and following relapses in localities where there *is no initial malaria and 79 per cent of* these were simple tertians, over 20 per cent malignant tertians and only a small fraction quartans The generally accepted statement also that perniciousness is confined to malignant tertian is opposed to one's experience as one has seen such conditions as algid paroxysms *choleraic attacks cerebral attacks* and even hyperpyrexial phenomena associated with simple tertian infection whilst a fair proportion of cases of repeated simple tertian relapses or reinfections end in malarial cachexia In discussing the subject with medical men of wide knowledge of Indian malaria it has been ascertained that one's experience in this respect is not exceptional

4 I am *not altogether* satisfied that *an* incontestible case has been made out by Major Acton *for* the exclusive use of the combined cinchona *alkaloids* (we used to call them the *mixed alkaloids* 30 odd years *ago*) in benign tertian infection, but he has shown rather forcibly that they should be subjected to a further extensive trial carried out on scientific lines They were very largely used in the out patient department of the Medical College Hospital Calcutta, a *generation ago, where we had about 100 cases of malarial infection attending every morning, and one remembers that a fair proportion of these cases rejected their dose shortly* after swallowing it The use of tablets of the mixed alkaloids as suggested by Major Acton, would probably to some extent remove this disadvantage

Two sections of the paper under reference—The Effect of the Total Alkaloids of Cinchona Bark on Benign Tertian Infections and Effect of the Cinchona Alkaloids on Benign Tertian Infections—are of profound interest They deal with an aspect of the therapeutic uses of the products of the cinchona bark regarding which we have been too long in ignorance, and they indicate the necessity of combining the work of a highly trained chemist with that of clinicians and parasitologists in medical institutions carrying out original researches on malaria in India It appears to me that the work which Major Acton has been doing in connexion with the mixed alkaloids might with great advantage be extended to inquiries regarding several of the individual alkaloids of cinchona bark

I was very pleased to notice that Major Acton considers that the microscope is not sufficiently employed in the diagnosis of malarial infections in India

It is specially gratifying to learn that Major Acton is now labouring at home endeavouring to give practical application to the excellent work he was doing at Dagshai —I am, Sir, yours faithfully,

P HEHIR,
London, June 14th 1920 Major General I M S (retired)

ABDOMINAL EMERGENCIES.

To the Editor of THE LANCET

SIR,—I beg to be excused for sending so belated a reply to Mr A G T. Fisher's criticism (April 17th) of my paper on Abdominal Emergencies published in THE LANCET of April 10th Several points struck me at once on reading it

1 He had evidently not read the cases carefully

2 He had missed the chief point of the paper—viz, a plea for an exact diagnosis, and the natural outcome of this, to act on the diagnosis made

3 The cases he mentions convey quite a different impression in his description than they do from reading my notes of them, in other words, he gives them the complexion he wishes them to have

4 His opinion appears to be based entirely on statistics he has been able to collect, and in no place does he lead me to suppose that he has had any personal experience in "civil" abdominal emergencies

5 *I feel that his remarks are, to say the least ungenerous when he applies such terms as "apparently" "gambler's throw," and "considered to be"* to what we considered at the time as definite diagnoses

Apart from this, perhaps I may be allowed to comment on his letter In ruptured duodenal ulcers he has apparently not seen a case such as we diagnosed No 15 to be, although they are by no means rare, and within a fortnight of writing the published paper I had another This was a patient, aged 25, admitted six hours after perforation He was diagnosed correctly in detail by the house surgeon and myself independently, he was operated on at once and the diagnosis confirmed, the ulcer presenting a minute perforation which was already closed *The fact, too, of Case 15 being perforated 36 hours seems to mean nothing to him, and* in his consideration of statistics he has overlooked the relative recovery rate, according to the interval between perforation and operation

From his criticism of Case 1, the appendix abscess which was left alone, two conclusions are obvious (1) in such cases the frequent passage of small quantities of mucus conveys nothing to him, and (2) he did not accept the diagnosis that the abscess was "pointing" in the upper part of the rectum, although this was verified within 24 hours

In reference to his criticism of Case 2 the female child with *pneumococcal peritonitis,* I should like to ask him what operation he thinks would be of any use in such a case If he is thinking of drainage, I should have thought that his experience as surgical specialist R A M C, would have taught him the futility of a drainage tube in a diffuse infection of the peritoneal cavity, where no large quantity of free fluid was present

Perhaps, too, it is permissible to remind him that the peritonitis in such cases is only one of the manifestations of the pneumococcal infection, and possibly the incision of the belly wall may be even harmful, as interfering in some measure with the respiratory movements.

Finally, may I recall to him my second concluding remark—viz.: "No hard-and-fast rules can be made; general principles ought to be laid down and followed, and special features of individual cases must be taken into consideration before a final decision as to treatment can be adopted."—I am, Sir, yours faithfully,

CHARLES F. M. SAINT,
Professor of Surgery, University of Cape Town.
May 20th, 1920.

GASTRO-ENTEROSTOMY: DIETETIC VALUE OF ALCOHOL.

To the Editor of THE LANCET.

SIR,—As a confirmed gastro-enterostomist of some years' standing I wish to express admiration for Mr. H. J. Paterson's lucid exposition, at a recent meeting of the Section of Surgery of the Royal Society of Medicine,[1] of the rationale of this operation; my personal experience is in accordance with that of Mr. Paterson as to the application and success of the procedure. Also I was deeply interested in reading Mr. A. J. Walton's dark roll of surgical iniquity, which I am sure will command profound study by all who are responsible for the efficient training of surgeons. At the same time I do not wish to infer that, although I happened to escape from inclusion in that roll, I have not had my share of compensatory, post-operative trouble, the principal one being a two-year plague of diffuse, dense iodine peritoneal adhesions, some of which caused intestinal obstruction, with three fatalities. The abandonment of iodine skin disinfection and return to old friends—alcohol mercurial lotion, and careful adjustment of isolating towels in and around parietal wounds by Mr. Marmaduke Sheild's through-and-through retractor silk sutures—relieved a situation which was really becoming intolerable.

It is not my desire to occupy space in reiteration of what I have already published on this subject further than to mention that my ideas on the operation of gastro-enterostomy are recorded in THE LANCET of Oct. 26th, 1912, and it is possible that the method therein described may now merit some attention. I think it a duty to repeat that in my opinion the employment of clamps in gastro-enterostomy violates the rudiments of operative surgery, in that they entail a needless traumatic insult to the delicate visceral structures, and a fatuous, if not culpable, obfuscation of potential hæmorrhage from many important vessels which must be injured in the course of the necessary incisions. I have no hesitation, judging from the number of fatalities which occur from post-operative hæmatemesis, in craving for the attention of surgeons to what I maintain is a preventable catastrophe—and, moreover, I consider it a disgrace to surgery and a parody on human reason that the term "hæmostatic through-and-through stitch" should ever have been countenanced in the surgery of the stomach. And I strongly recommend anyone who has not time or nerve openly to tackle the dozen or so bleeding vessels which usually demand ligature before the insertion of the inner circular catgut suture to transfer such cases to a colleague.

I am not of those who discount the importance of time,[2] yet I wish to emphasise that I am unable to follow the mentality that admits, in gastric surgery, of the repudiation of the cardinal rule—see the bleeding point and tie it. With all deference I beg of the authors of operative text-books to give this view some more reflection in the hope that they may see their way to delete some of the irons which now adorn their illustrations, and to bring a needle and thread into better perspective with an artery forceps and ligature well in the foreground.

There is another item which has for years baffled my sense of comprehension—the inordinate haste to get these patients out of bed and to introduce solid food into doubly lesioned stomachs. Apart from direct and peristaltic traumatism, apart from the very negation of Hilton's law, apart from the fact that it takes at least 14 days for *restitutio ad integrum* of any solution of continuity in the human body, the early administration of solid food is a physiological anachronism in that it induces the gastric glands to pour forth an abundance of acid secretion at the moment when the organ is extra-handicapped with an additional six-inch gastric sore, and when, by all the rules, an alkaline state is necessary for its salvation. Recently, I was gratified to read that Dr. T. G. Moorhead, of Dublin, had called attention to this matter, and I hope his opinions will exact the consideration which they always deserve.

It has been my plan for many years, a few days after operation, to hand over these cases to the sister's personal care, with the injunction that they shall be kept in bed and on a rigid milk diet (plus mist. carbonatis ter die) until the 28th day. Before discharge each one receives instructions as to what he should eat and drink during the ensuing year, and invariably some alcoholic stimulant is recommended at lunch and dinner.

It may not be reckoned irrelevant if I touch on the prophylactic treatment of this too prevalent malady, and in order to avoid prolixity or getting out of depth I will briefly mention "Ten Commandments!" which I have found of great service to candidates for gastric ulcer, who, perforce, have to lead a sedentary existence with comparatively little out-door exercise.

I. As a general rule, indulge only in two meals a day, and take only two plates to each meal—meat with vegetables, and fruit with or without light milk pudding, or cheese.

II. Masticate thoroughly, have rotten "stumps" extracted.

III. Take—in moderation—whatever alcoholic beverage is most congenial to your stomach—i.e., which does not, hours afterwards, create excessive acidity or a feeling of "liver."

IV. Whenever practicable, rest mind and body for one hour after a meat lunch in order to allow the digestive machine to get the wind up before an extra call for blood is made by brain or muscles.

V. Allow at least a six-hour interval between mid-day and evening meals.

VI. Do not pollute the refreshing cup of afternoon tea with bread and butter, cakes, scones, or other decomposing fermenting carbohydrate messes which deprive the unfortunate stomach of all chance of a rest before it has to tackle its dinner problem.

VII. Abjure the use of any form of alcoholic refreshment except at your lunch and dinner table.

VIII. Whenever *feasible take a stroll in the evening* after dinner, and sleep in a room with a large open window—not in a draught—so that the blood may be properly oxygenated during the eight hours of repose.

IX. Make it a creed to take regular morning exercise. Begin with a hard snap of shadow-boxing (commence with 20 and work gradually up to 100 double clouts) in order to extend the heart muscle and elastic tissue of the lungs. Follow with, e.g., Muller's eight physical exercises, then have a cold shower-bath, and promptly conclude with Muller's excellent towel drill before some open door or window.

X. "Dulce est desipere in loco"—but not too often.

I am aware that I tread on delicate ground in advocating the general moderate use of alcoholic drink with meals. In response to the "Hallelujah" cantations of ascetic mummers whose psychological diapason is solely comprised of one hyphenated falsetto—to eradicate an abuse it is necessary to lop off the use—I have no compunction in affirming that the rational dietetic use of the fermented juice of the grape, of the hop, and of some cereals is a "god-send" to man's digestion, and that while the indiscriminate use or bestial abuse of same unquestionably speeds down to the grave, universal total abstention would tend, in a comparatively short cycle of time, to depopulate the earth, and, in all probability, would compel whatever might remain with human form ultimately to seek refuge in the Simian freedom of an arboreal existence.

The die is cast—the test is now being applied on a large scale—may I beg my readers and their descendants carefully to note and compare, in the respective wet and dry zones, the future incidence of tuberculosis, cancer, lunacy, diabetes, resistance to infection, addiction to drug habit, and frequent and prolonged tours abroad for business, health, and pleasure purposes.

I am, Sir, yours faithfully,

JOHN O'CONOR, M.A., M.D. T.C.D.,
Senior Medical Officer, British Hospital, Buenos Aires.
April 14th, 1920.

THE PLACE OF NORMAL PSYCHOLOGY IN MEDICAL EDUCATION

To the Editor of THE LANCET

SIR,—In your issue of June 19th you publish a report of the Education Committee of the General Council of Medical Education and Registration, in which it is stated that the majority of the bodies consulted hold that "some instruction ' in normal psychology ' should be given by the lecturer in mental diseases as a prelude to his course ' I wish to protest very strongly against this proposed position of normal psychology in the medical curriculum Why should the functions of the normal human *mind* be taught at a period so remote from that at which the student receives instruction in the functions of the normal human *body*? A course on normal psychology should follow immediately on that of physiology, when the student has the facts of the structure and functions of the sense organs and central nervous system fresh in his mind Why should psychology stand in the unique position of having its normal and pathological aspects taught at the same time? Why should "psychological medicine receive different treatment in the medical curriculum from "somatic" medicine, surgery, or midwifery? As well might the pharmacologist be asked to give some lectures on botany and chemistry, the pathologist some lectures on physiology, chemistry, and anatomy, "as a prelude to his course " I am, Sir, yours faithfully,

Montagu square W June 20th 1920 CHARLES S MYERS

THE IMPORTANCE OF IMMEDIATE SELF DISINFECTION

To the Editor of THE LANCET

SIR,—Mr H Wansey Bayly's letter published in your last issue will have corrected the wrong impression that the digest of my speech in your previous issue would convey with regard to my remarks about disinfectant centres No doubt if all those who indulged in promiscuous sexual intercourse could be induced, whatever the weather and the circumstances, to hurry to a disinfectant centre, provided there was one handy, and were there treated by a skilled attendant within one hour of the connexion, many venereal infections would be prevented But the provision of a sufficient number of these centres bristles with difficulties In order to comply with the time limit, which is the vital essence of disinfection, they would have to be so numerously provided as to make an adequate provision prohibitive There remains the danger of espionage and blackmail, which in rural districts would be very real

But leaving speculation on one side, the fact remains that the number of disinfectant centres already provided is negligible, while venereal infection is proceeding For this reason the S P V D is determined to push forward its policy of instruction in the methods of immediate self disinfection rather than wait for the universal establishment of disinfectant centres, where at its best the disinfection would be delayed

I am, Sir, yours faithfully,

June 20th 1920 WILLOUGHBY DE BROKE

THE STANDARDISATION OF COLOUR PERCEPTION

To the Editor of THE LANCET

SIR,—A certain amount of dogmatism is not only condoned, but is even desirable, in a student's text book I admit, however, that the statements quoted by Dr Edridge Green from the second edition of my "Diseases of the Eye" are open to serious criticism They have been modified as follows in the third edition —

> Only those of large experience will gather any useful information from the names given by the subject to various colours for these are named chiefly by reference to their various brightnesses and the answers appear to be quite inconsistent In testing for danger only it is obvious that the names given to the colours are of value for if a man repeatedly calls red green or vice versâ he is clearly unsuited to be an engine-driver or look-out man on a ship Holmgren s wools have been much criticised but if the tests are properly carried out gross defects of colour vision are easily recognised and an expert will be put on his guard in almost every case of even minor defect

But is Dr Edridge Green so opposed to Holmgren's test as his statement that it is "obsolete" would imply? Surely his classification test, which still figures in his latest book, is a direct descendant of the Holmgren test, just as his lantern is a modification—and great improvement—on previous lanterns which had been used for the detection of colour blindness, his bead test a modification of Sir Wm Abney s bead test, and his card test a modification of Stilling s test Of course, the application of a new principle to old tests gives those tests an entirely new meaning The crux of the situation is whether the principle can be substantiated In other words, if the scientific evidence is against Dr Edridge Green's theories the whole of the rest of the discussion *is beating about the bush*

Dr Edridge Green s remark that I am now using his methods is characteristic of his mode of controversy If to use a lantern for testing colour vision is using his method, then Holmgren and Donders used his method before he began to write on the subject But just as I use Nagel s, and Stilling s, and Abney s methods, so I am perfectly prepared to use Dr Edridge Green s or anyone else's if they appear to me to help in the elucidation of a very difficult problem

I am, Sir, yours faithfully

J HERBERT PARSONS

Queen Anne street Cavendish square W June 19th 1920

To the Editor of THE LANCET

SIR,—The papers referred to by Mr Parsons in the Proceedings of the Royal Society, 1910, can be read by anyone, who can then judge for himself whether the point raised by Lord Rayleigh and supported by Dr William Watson was "conclusively proved ' I am inclined to think that here few would agree with Mr Parsons Dr Edridge Green read his paper on the theory of vision at the International Medical Congress at Budapest in 1909 This was read, by request, in two sections, the ophthalmological and the physiological There was not a word of adverse criticism in either section, but the strongest approval Professor von Tschermak, professor of physiology in Vienna and one of the leading authorities on vision, subsequently wrote to THE LANCET (Oct 30th, 1909) strongly supporting the theory I am, Sir, yours faithfully,

Wimpole street W June 21st 1920 PERCY DUNN

THE RÔLE OF REPRESSION IN THE WAR NEUROSES

To the Editor of THE LANCET

SIR,—With all deference to so eminent an authority as Sir James Crichton Browne, his remarks (THE LANCET, June 12th, p 1296) on what he terms the "anti repression method" of dealing with the war neuroses are not in accord with the actual experiences of many psychotherapists On the contrary, the more one sees of these cases the more one is convinced that amidst the mass of bewildering theories advanced the importance of repression in the production and maintenance of symptoms becomes daily more evident

Psychotherapists will probably agree with Sir James Crichton Browne's statement of the concept of repression in the paper referred to but when he states that patients are told to "keep their miseries ever before them" it may well be asked Whose teaching this is? It is certainly not that of Dr W H R Rivers who cites, only to condemn, the case of an officer with a tendency to dwell overmuch on his war memories

It is a matter of actual experience that in a majority of the genuine war cases admitted even at this period to neurological hospitals, the patient on being interrogated states that his aim is to banish the war from his memory, if he hears it discussed he leaves the room He says that nothing would induce him to attend such a function as a soldiers' reunion in his town where he would meet with his old comrades In short, he is vigorously repressing his war memories He almost invariably complains of dreaming about the very events he puts out of his mind in the day time, and this is corroborated by the night staff and by other patients who hear the words shouted in the nightmare

There is a common misapprehension on the part of those interested in these cases as to the attitude of the psychotherapist towards repression He wishes the war to be forgotten as much as does the patient, but the difference is in the method best calculated to attain this end. If a farcical and, perhaps, absurd analogy, which nevertheless appeals to patients, may be allowed, their attitude towards their war experiences is that of a young child who has been told by a foolish nurse that a jack-in-the-box contains a bogey-man with power to jump out and hurt him if he is troublesome. If left alone with this and his toys—and it has to be imagined that the hook which keeps the lid of the box down is broken—the child, afraid of the bogey's eruption, keeps the lid down by the force of his hand. All goes more or less well until fatigue and drowsiness supervene, whereon the hand drops off, the doll jumps out, and the child is terror-struck. (It is significant how many patients tell one they wake with a start, sweating and palpitating, just as sleep overtakes them with its suspension of the power of the will to act as censor.)

Will it be said that in such a case it would be at "variance with common sense" to take the child to the dreaded box, to open it and to show him that the awesome bogey is only a harmless doll, and are not war memories equally harmless, if he will only realise it, to a patient safely back in England? The child, once realising the innocuous nature of his bugbear, forgets it as soon as a new toy is given him, not because he wishes to drive it from his memory, but simply because it takes its proper place in his scheme of things, and has no particular emotional tone associated with it. So with the war neurotic; one aims at enabling him to forget his experiences by their taking their rightful place as memories admittedly terrible, but not worth running away from, and powerless to hurt him. There is indubitable evidence that when repression is genuinely overcome, the battle-dreams diminish, the patient sleeps better and soon begins to mend.

My reason for trespassing on your space is that, unfortunately, the advice invariably given to these patients is to forget the war and all about it, no doubt excellent advice if it worked. The fact that 20 months after the armistice and perhaps three, four, or even five years after the breakdown the men are still uncured shows sufficiently that it does not work.

I am, Sir, yours faithfully,
R. L. GAMLEN.
Brinnington Neurological Hospital, Stockport, June 15th, 1920.

THE SURGICAL TREATMENT OF PROLAPSE OF THE UTERUS AND VAGINA.

To the Editor of THE LANCET.

SIR,—I have read Dr. Blair Bell's letter. I regret very much his invective, which I do not answer. The aim of my first letter was to further science; Dr. Blair Bell's present letter adds nothing to the subject. I have neither the time nor the inclination to exchange vituperation; but this does not imply that I have received any reason to alter my views.

I am, Sir, yours faithfully,
Rugby, June 19th, 1920. R. H. PARAMORE.

THE CHEMO-THERAPEUTICS OF QUININE.

To the Editor of THE LANCET.

SIR,—The recent publication of Major H. W. Acton, I.M.S., which appeared in THE LANCET of June 12th, marks an important progress in the chemo-therapeutics of quinine. His observations that whilst the lævo-rotatory alkaloid quinine is a specific for the malignant tertian parasite its dextrorotatory isomeride quinidin is the best alkaloid for the benign tertian parasite deserve the greatest attention of those engaged in the treatment of malaria, since they open a new field for research on those lines.

In view of the importance of these observations I hope I may be permitted to describe a few chemical experiments which I was unfortunately unable to complete prior to my being demobilised from the army. These observations may be of some use to others.

(1) If a 10 per cent. solution of quinine sulphate is heated for one to two hours the solution turns dark. Its specific rotation falls from – 164° to – 43°. This depression of the rotation is probably due to the formation of quintoxin, as can be shown by the test described by v. Miller and Rhode. for this substance (*Berichte der deutschen chemischen Gesellschaft*, 1895, vol. xxviii., pp. 1058; 1900, vol. xxxiii., pp. 3223; compare also Scholz, *Berichte der deutschen pharmacologischen Gesellschaft*, 1908, vol. xviii., pp. 44).

(2) If, however, a 10 per cent. solution of quinine is heated for the same length of time and hydrogen or carbon dioxide is passed through the boiling solution all the time, the rotation alters from – 164° to + 58°. The solution does not alter in colour and is free from quintoxin.

I am inclined to think that by the second method quinine becomes partially isomerised to quinidin. This will be difficult to prove chemically, but it seems to me that it might, perhaps, be advisable to try such a method of "activating" quinine, since it is possible that it might possess the therapeutical advantages indicated by the observations made by Major Acton.

I am, Sir, yours faithfully,
M. NIERENSTEIN, D.Sc., Ph.D.,
Lecturer in Bio-chemistry.
University of Bristol, June 15th, 1920.

THE POSITION OF VETERINARY SCIENCE.

To the Editor of THE LANCET.

SIR,—I am sure that those who are really interested in the progress of veterinary science will be very grateful for the exceedingly sane leader in your issue of June 19th, which is in pleasant contrast to the semi-hysterical and partly erroneous lucubrations that have recently appeared in the daily press. There is, however, one omission to which I should like to draw your attention. You do not state that the University of Edinburgh confers the degrees of B.Sc. and D.Sc. in veterinary science. The ordinance under which these degrees are conferred came into operation in 1911, and the number of students taking the necessary additional courses of instruction now forms a considerable percentage of the Edinburgh veterinary students.

I might add, also, that the Royal College of Veterinary Surgeons has recently instituted a diploma in veterinary State medicine (D.V.S.M.), the first examination for which is to be held in Edinburgh during next week.

I am, Sir, yours faithfully,
O. CHARNOCK BRADLEY,
Principal, Royal (Dick) Veterinary College, Edinburgh.
June 19th, 1920.

INFANT INTOLERANCE TO COW'S MILK.

To the Editor of THE LANCET.

SIR,—The note from the Paris Correspondent of THE LANCET in your issue of June 12th on anaphylactic vomiting in an infant reminds me of a case of infant intolerance to cow's milk which was under my care. This child was born on Jan. 31st, 1913. He was breast-fed from birth. During the third month an attempt was made to begin feeding him with diluted sterilised cow's milk, prepared under my supervision. Within a few minutes he vomited the feed and came out in a profuse urticarial rash. The gastric disturbance lasted for a good many hours. The same thing happened with diluted pasteurised cow's milk from another dairy, which was tried a few days later, and a third attempt in July was no more successful. Cow's milk of varying strengths, including solutions of dried milk, was tried from time to time during the summer, but every attempt produced vomiting, rash, and gastric upset. In August we tried goat's milk with complete success, and for the next month the child had breast feeds and goat's milk—half of each. On Sept. 14th, 1913, he was weaned and was fed wholly on goat's milk until March 1st, 1914, when for the first time he began to tolerate diluted cow's milk in very small quantities. The amount of the cow's milk was gradually increased, and at the end of a month he could take undiluted cow's milk without any ill-effect. Thenceforward there was never any intolerance to cow's milk. It appears that a maternal aunt of this child was brought up on goat's milk "because she couldn't digest cow's milk"; there is no other relevant family history.

I am, Sir, yours faithfully,
London, June 19th, 1920. M.B., B.CH.

SOCIETY FOR THE PREVENTION OF VENEREAL DISEASE.—We have received a letter from Mr. Wansey Bayly, honorary secretary of this society, in which he states that the Executive Committee of the Society, at its last meeting, resolved that notice should be sent to all the medical members of the Executive, Medical, and Propaganda Committees of the National Council for Combating Venereal Diseases, and to the medical press, announcing the resignation from the National Council of Dr. Rayner D. Batten, Mr. E. T. Burke, Sir Bryan Donkin, Sir Frederick Mott, Sir Humphry Rolleston, and Dr. J. H. Sequeira.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND —As the result of the Final Fellowship Examination held from May 13th to 26th, for which 106 candidates presented themselves, 38 candidates were approved, including one woman The Council accordingly, at its meeting on June 10th, conferred the diploma of Fellow on these candidates also upon one candidate (Mr W E L Clark) who had previously passed the requisite examinations, and has now attained the age of 25 years The following are the names and medical schools of the successful candidates —

James Wilmot Adams St Bart s Hosp August Lyle Buchanan Sydney Univ and London Hosp Neil Canthe Aberdeen Univ and Charing Cross Hosp Wilfrid Edward Le Gros Clark St Thomas s Hosp John Henry Cobb Sheffield Univ and Middlesex Hosp Harold Robert Dew Melbourne Univ and London Hosp Sidney Forsdike Univ Coll Hosp Robert Fowler Melbourne Univ and London Hosp John Frederic Gill Aberdeen Univ and London Hosp John Gilmour Durham Univ and London Hosp John Richard Griffith Cambridge Univ and St Bart s Hosp George Gushue-Taylor London Hosp Ranald Montagu Handfield-Jones St Mary s Hosp James Norman Jackson Hartley Edinburgh Univ Lionel George Higgins Cambridge Univ and St Thomas s Hosp Arthur Norman Hooper Cambridge and Birmingham Univs and Middlesex Hosp John Basil Hume St Bart s Hosp Jack Joffe Guy s Hosp Robert Andrew Kerr Belfast and London Hosp Muriel Elsie Landau Royal Free Hosp Kenneth Holl McMillan St Thomas s Hosp Francis Courteney Mason Middlesex Hosp Abdel Wahhab Mooro Cairo and St Bart s Hosp Thomas Paterson Noble Edinburgh Univ and London Hosp William Heneage Ogilvie Oxford Univ and Guy s Hosp Alan Cecil Perry London Hosp Leslie Norman Reece St Thomas s Hosp Cedric Sydney Lane Roberts Guy s Hosp Thomas Lewis Lindsay Sandes Dublin Univ , Bernard Sangster Simmonds Middlesex and St Bart s Hosps Neil Frederick Sinclair London Hosp Clive Nigel Smith Sydney Univ and Middlesex Hosp William Edward Mandall Wardill Durham and London Hosp William Turner Warwick and Maurice Henry Whiting Cambridge Univ and Middlesex Hosp John Whittingdale Cambridge Univ and St Bart s Hosp Nathan Judah Wigram Sheffield Univ and Lond Hosp Frederick Arnold Williamson Cambridge Univ and St Mary s Hosp and Henry Wardel Snarey Wright University Coll Hosp

Licences in Dental Surgery were also conferred upon the following 21 candidates who have passed the requisite examinations and have complied with the by laws —

W S Beauchamp London Evelyn Olive Betts National Dental H F Buchan Bristol H J Cavanagh National Dental R L Close Royal Dental A R Cox and D M Desai Guy s G A N Dod and H R Evans Royal Dental G H Froggatt Sheffield N Gerson Guy s R B Gibson Sheffield J R Humphreys Liverpool Margherita Maria Loretz Univ Coll C A Marais Guy s M Miliaressis Royal Dental T W Mitchell National Dental W H L Phillips Birmingham A E Poole Sheffield and Royal Dental A F Rees National Dental and G W Wilson Royal Dental

ROYAL COLLEGE OF PHYSICIANS OF IRELAND —The following have been admitted as Licentiates and Members of the College Robert Marshall, M B B Ch Q U Belfast, Uma Prasanna Basu M B Calcutta

UNIVERSITY OF LONDON, UNIVERSITY COLLEGE — There will be an assembly of the College Faculties on Friday next July 2nd at 2 30 P M when the American Ambassador, Mr John W Davis will receive the newly elected Fellows the scholars medallists, and prizemen and will address the assembly Graduates and undergraduates are requested to wear academic costume Later there will be an installation by the Ambassador of the collection of books on American History and Institutions presented by the Carnegie Endowment for International Peace and a concert by the students The college libraries museums and laboratories will be open to inspection

PROVISION OF EXPERT MEDICAL AND SURGICAL SERVICES —A paper read before the Society of Medical Officers of Health on May 28th by Dr A H Bygott county medical officer for West Suffolk dwelt on the provision of expert medical and surgical services from the point of view of the medical officer of health Dr Bygott emphasised the need of improved organisation of medical services and of the facilities for in patient and out patient institutional treatment throughout the country, as both the medical profession and the public were dissatisfied with the present state of things He drew attention to what he considered the unsatisfactory conditions of the present hospital system based on charity rather than on the conception of the hospital as the centre of the medical life of the area He deplored also the ignorance of the general public with regard to the incidence of diseases and the lack of opportunity for the general practitioner to consult with specialists Dr Bygott sketched out a scheme for improved organisation in these directions, which included suggestions for the better utilisation of the services of the members of the junior staff of the teaching school hospitals

SEAMEN'S HOSPITAL SOCIETY.—On Monday next, June 28th, at 2 P M , Sir Leonard Rogers is giving a lecture at the London School of Tropical Medicine Endsleigh Gardens N W on Leprosy On July 14th, at the same hour and place Colonel S P James will lecture on the Prevention of Malaria, and members of the medical profession will be welcome on both occasions

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION — A meeting of this association will be held at 11 Chandos street Cavendish square W , on Monday next, June 28th at 5 15 P M when Mr R W Tustin, late Chairman of the Milk Committee of the Canadian Food Control Board, will give a lecture on Milk supply illustrated by the kinematograph and lantern slides All interested in the subject are invited to be present

A SINGLE EXAMINATION FOR GOVERNMENT MEDICAL SERVICE —At a meeting of the Conference of Delegates of the Metropolitan Medical Schools held on March 11th, the following resolution was passed —

> That application be made to the Government requesting that a single examination be instituted for admission to the Medical Services of all Government Departments and that this examination be held at regular intervals

The individual medical schools were invited to consider this question and at a meeting of the Conference held on June 2nd it was resolved that the proposal be approved in principle and that the departments concerned be informed and asked to communicate the details of any arrangements which might be formulated if it were decided to institute a single examination Mr A E Webb-Johnson, honorary secretary to the Conference of Delegates informs us that a letter conveying the above has now been sent to the Government Departments concerned

LITERARY INTELLIGENCE.—The Cambridge University Press announce for immediate publication "Industrial Colonies and Village Settlements for the Consumptive," by Sir German Sims Woodhead and Mr. P. C. Varrier-Jones, the honorary medical officer of the Cambridge Tuberculosis Colony at Papworth, with a preface by Sir Clifford Allbutt.

GREAT NORTHERN CENTRAL HOSPITAL, HOLLOWAY-ROAD, LONDON.—The chairman, the Marquess of Northampton, will receive visitors in the board-room on View Day, Thursday, July 1st, at 3 P.M. The wards can be visited from 3 to 4.30 P.M.

THE FEDERATION OF MEDICAL AND ALLIED SOCIETIES.—At a meeting of the Gloucestershire branch of the British Medical Association held on June 17th the following resolution was carried unanimously:—

> "That it is the desire of the Gloucestershire branch that the British Medical Association agree to appoint accredited representatives of the Association to the Federation of Medical and Allied Societies."

THE Incorporated Society of Trained Masseuses and the Institute of Massage and Remedial Gymnastics have amalgamated, and under the Royal Charter, which has been granted, the amalgamation of the two societies will be styled The Chartered Society of Massage and Medical Gymnastics.

MINISTRY OF PENSIONS HOSPITAL, BATH.—The new department of psychotherapy, an enlargement of the orthopædic block of the Ministry of Pensions Hospital, Bath, of which Mr. E. W. Hey Groves is the surgical director, was opened on June 3rd by Sir Robert Jones.

VACCINATION DIFFICULTIES IN DEVONSHIRE.—At the last meeting of the Crediton (Devon) urban council allusion was made to the increasing number of applications for exemptions from vaccination, and it was suggested that they should be less easily obtainable. It was decided to request the Urban Councils' Association to consider the matter.

MEDICAL MAGISTRATES.—Mr. Reginald Whiteside Statham, M.R.C.S., L.S.A., of the Hall, Cheddar, has been placed on the commission of the peace for the county of Somerset.—Mr. Dudley Raymond Harris, L.R.C.P., M.R.C.S., has been placed on the commission of the peace for the borough of Dartmouth (Devon).

MEMORIAL TO A SOUTH AFRICAN MEDICAL MAN.—A tablet in the Parliament House, Capetown, in memory of Dr. R. A. Buntine, M.L.A., of Pietermaritzburg, Natal, who was drowned when the R.M.S. *Galway Castle* was torpedoed two years ago, was recently unveiled by General Smuts.

LISKEARD (CORNWALL) COTTAGE HOSPITAL.—The Cornwall branch of the Red Cross Society has offered £250 to the Liskeard Cottage Hospital towards the provision of a new children's ward, conditionally on the same amount being subscribed locally before Dec. 31st next. The committee decided to appoint collectors to try to raise £250, and after that has been obtained to make a public appeal for a sum sufficient to build and furnish a new children's ward.

THE SANITARY INSPECTION OF DARTMOUTH.—The Dartmouth town council recently advertised for a municipal officer as "borough surveyor, water engineer, and inspector of nuisances." The Ministry of Health remonstrated and stated that the town required a whole-time inspector of nuisances, adding that the sanitary conditions of the town were "below the normal." At the last meeting of the town council it was reported that there were 60 applicants for the post. Some of the members urged that it was impossible for one man to do the work and that they should reconsider the matter. Eventually it was decided to defer the subject to another meeting. Dartmouth, which has a population of about 7000, would certainly appear to require the undivided attention of a sanitary inspector, and it is to be hoped that the council will reconsider the appointment and follow the wishes of the Health Ministry.

ENHAM VILLAGE CENTRE.—A garden fête for the purpose of raising funds to extend the work of this centre for disabled ex-service men will be opened by the Duke of Connaught on Wednesday, June 30th, at 2.45 P.M., and by the Countess of Bective on Thursday, July 1st, at 2 P.M. It will be remembered that the estate comprises over 1000 acres and was purchased and equipped by voluntary contributions for treatment and training purposes. Its beautiful situation makes it an ideal place for providing small holdings and village industries for permanently disabled men. Conveyances will be available to and from Andover Junction on the days of the fête; admission will be 1*s*., and after 6 P.M. 6*d*. The programme includes a bazaar, pastoral play, morris dances, side shows, Punch and Judy show, dancing, tea and refreshments, military bands, and the E.V.C. orchestra in the grounds of Enham Place. It is hoped that a large attendance will be secured.

Mr. Roy Neville Craig, L.R.C.P. Lond., M.R.C.S., L.M.S.S.A., has been elected a member of the Torquay town council.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the committee, held on June 8th, 13 cases were considered, and £138 voted to 10 of the applicants. The following is a summary of some of the cases relieved:—

Widow, aged 77, of M.D. Lond. who practised at Penzance and died in 1899. Has two daughters, aged 51 and 38; the elder attends to the home and the younger is an invalid. Income from leasehold property, £170 per annum, a large portion of which goes on repairs, £60 having been paid since March. The lease of two houses will fall through in four years. Rent, £17, and rates on one house, £26. Have had to sell one house during the last 12 months, to meet the expenses of dilapidations and repairs. High cost of living is making it impossible to make ends meet. Voted £18 in 12 instalments.—Daughter, aged 72, of L.S.A. Lond. who practised at Lambeth and died in 1884. In the past herself and invalid brother have managed to live on the proceeds of some property, but the leases all expired in June of this year. Their joint income has never exceeded more than £100 a year; consequently they have been unable to save, and their income will now practically cease. Voted £26 in 12 instalments.—Widow, aged 60, of M.R.C.S. Eng. who practised at Dover and died in 1916. Applicant was left with two daughters, now aged 19 and 18, who are students, and will not be able to earn for at least another year. Applicant has a position as housekeeper, and the daughters are allowed to live with her. Friends help with tuition fees, but practically all the applicant's earnings are taken to provide the balance. Relieved three times, £30. Voted £10.—Daughter, aged 63, of M.R.C.S. Eng. who practised at Long Sutton and died in 1877. Only income about £25 from investments. Has acted for many years as housekeeper to a gentleman, but he has died. At present she is looking after his sons, and receiving board and lodging for her services. Suffers from ill-health. Relieved five times, £60. Voted £12 in 12 instalments.—Daughter, aged 81, of M.R.C.S. Eng. who practised at Hackney and died in 1859. She suffers from ill-health, and is now losing the sight of one eye. She receives about £78 from friends and £30 from another charity. Relieved eight times, £111. Voted £20 in 12 instalments.—Daughter, aged 59, of M.R.C.S. Eng. who practised at St. Day and died in 1917. Daughter looked after her father until his death, and then found it difficult to commence to earn her living. Acts as organist at the church, and receives £14 a year, and about £6 by teaching music. Rent and rates £16 16*s*. Relieved three times, £36. Voted £18 in 12 instalments.

Subscriptions may be sent to the honorary treasurer, Sir Charters Symonds, K.B.E., C.B., F.R.C.S., at 11, Chandos-street, Cavendish-square, London, W.1.

POST-GRADUATE WORK IN PARIS.—An interesting programme of the second series of a holiday course of lectures, called "Improvement Course" for 1919-20, has just been published by the Medical Faculty of the University of Paris. The lectures, held in the Trousseau and Bichat lecture-rooms of the Hôtel Dieu Hospital, Place Notre Dame, begin on July 10th at 9 A.M., the entire course of 31 lectures being completed in two weeks, when a certificate will be given to each student. Four of these holiday lecture courses are held every year at the Hôtel Dieu, the two improvement courses (Cours de Perfectionnement) taking place at the Easter and summer vacations, and the other two, called Revision Courses, at the New Year and in October. The July course is under the direction of Professor Maurice Villaret, assisted by MM. Lardennois, Herscher, Lippmann, Chabrol, Francois Moutier, Henri Bénard, Saint-Girons, Paul Descomps, Deval, Guilleminot, Durey, and Dausset. The subject of the July programme is "Recent Ideas on the Diagnosis and Therapeutics of Diseases of the Digestive Apparatus," and the lectures are divided into four sections, entitled: (1) Investigation; (2) Symptoms; (3) Diseases; (4) Treatment. The lectures take place daily from 9 to 10 in the morning and from 2.30 to 5.30 in the afternoon. A detailed summary of each lecture is issued to the students, and the course includes illustrations, with plates and lantern slides, and inspection of patients, instruments, and microscopic preparations, while special stress is laid on clinical instructions and on recent processes of medical, surgical, physio- and hydro-therapeutics. The students obtain individual tuition in the clinical examination and handling of patients, in the working of apparatus, and in laboratory research on the cases dealt with, with permission to take away their results. A specially interesting part of the programme is the three-day study tour arranged for July 14th, 15th, and 16th under the direction of Professor Gilbert and Professor Maurice Villaret, when a visit will be paid to Vichy and the hydro-mineral resorts in Auvergne. No charge of any kind will be made for this trip, either for railway, meals, hotels, or motors. For admission to the course of lectures at the Hôtel Dieu a laboratory fee has been fixed at 150 francs, to be paid in advance at No. 3 window of the secretary's office in the Medical Faculty on Tuesdays, Thursdays, and Saturdays from 12 to 3 P.M. The general scheme of these lectures, which include two revision courses, one on the Effect of the War on Nerves, to be held in the New Year vacation, and the other on the Application of Laboratory Methods in Diagnosis, to be given in October, is rather broader than the usual post-graduate course, since the lectures are open to the matriculated students in the Faculty, as well as to all French and foreign doctors.

MINISTRY OF PENSIONS NURSING SERVICE—New rates of pay have been sanctioned for the Ministry of Pensions Nursing Service These rates are matrons £115 to £185, charge sisters, £75 to £85, nursing sisters, £60 to £65, assistant nurses £25 to £40 War service is counted towards increment in all ranks There are vacancies at present in the junior ranks, and application forms and further particulars may be obtained from the Matron in Chief, 14, Great Smith street, Westminster

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY, LTD—At the last meeting of the Council the following resolutions were unanimously passed —

1 In view of recent increases in charges incidental to litigation it is advisable that a corresponding increase should be made in the amount of the indemnity with regard thereto which may be granted to the members of the society in accordance with the terms and provisions of the Memorandum and Articles of Association

2 An indemnity up to the aggregate sum of £3000 in any one calendar year or such other sum as the Council may from time to time determine may be granted to members of the society on whose behalf litigation is undertaken or defended by the society in accordance with the terms and provisions of the Memorandum and Articles of Association

3 The cost of providing for the risk of the increased amount of indemnity by insurance or re insurance shall be charged against the society s Special Insurance Fund

DONATIONS AND BEQUESTS—The late Mr William Barwick Gregoe Colmore, of Cadogan place S W, has left by will £500 to the Cheltenham Hospital, £500 to the Birmingham General Hospital £200 each to the Queen's Hospital, Birmingham, the Birmingham General Dispensary, the General Institution for the Blind, Edgbaston, the Deaf and Dumb Institution, Edgbaston, the Children's Hospital, Birmingham, the Birmingham and Midland Eye Hospital, the Birmingham Orthopædic and Spinal Hospital and the Birmingham and Midland Counties Sanatorium £100 each to the Dental Hospital Birmingham, the Birmingham Lying in Charity, the Birmingham and Midland Homœopathic Hospital the Birmingham and Midland Counties Ear and Throat Hospital, the Birmingham and Midland Skin and Lock Hospital, and the Birmingham and Midland Hospital for Women

THE CORONERS' SOCIETY ANNUAL BANQUET—The annual meeting of the Coroners Society of England and Wales, held on June 10th was followed by a banquet at the Holborn Restaurant Mr Kelway Pope, coroner for Southampton, the newly elected President, proposed the loyal toasts after which Mr A M Forbes coroner for Middlesex, gave the toast of ' Imperial and Local Government," to which Major A Boyd Carpenter, M P, replied Mr Brooke Little who proposed the toast of 'The Coroners' Society," said the office of coroner was of very ancient origin It was known that coroners existed in 1194 and, according to some authorities, even earlier Coroners in early days had to be able to read and write and were elected by the popular vote The office was then unpaid, but in the time of Henry VII a sum of 13*s* 4*d* was paid to the coroner in all cases of murder and manslaughter out of the chattels of the accused, in the time of George II the payment of an increased fee for all inquests held upon view of dead bodies was ordained The object of the Coroners' Society was, said Mr Little, the protection of the rights and duties of coroners, and any recommendations by its members ought to carry weight At the present time there were over 30 outstanding enactments relating to coroners, which might well be included in one consolidating and amending Act Mr Pope having acknowledged the toast, Mr H R Oswald, coroner for the western district of London, proposed the toast of "Our Guests" Sir Edward Troup Permanent Under Secretary to the Home Office in reply, said that the Home Office hoped to deal with the question of coroner's juries as soon as possible The emergency legislation, giving the coroners power to dispense with juries held good for six months after the official termination of the war, and so long as the Turks procrastinated about making peace, so long, at least, would coroners be able to sit without juries He hoped it would be possible to deal generally with the jury question and other matters by way of legislation No complaints had been received from the general public regarding the holding of inquests without juries except in one case in which a coroner had returned a verdict of *felo-de se* Coroners generally appeared to like the discretionary powers entrusted to them Another question was whether a coroner should be a lawyer or a medical man He regarded it as a narrow view to confine the candidate for a coroner's office to two professions only During the next ten years at least he considered vacancies should be filled by men who had seen active service and he considered that coroners ought to be better paid In the higher ranks of the Home Office a war bonus was given, while the junior staff received 30 per cent increase in their pre war pay Sir Claud Schuster Permanent Secretary to the Lord Chancellor, also replied for the guests.

THE Academy of Medicine of Turin, in a recent private session, unanimously awarded the valuable Riberi prize to Dr Giuliano Vanghetti for his admirable researches on Amputations and Kinematic Prostheses These researches the Academy holds are destined enormously to relieve mutilations whether derived from war service or from the daily routine of labour The Academy further testifies that the work is the outcome of long and patient study, which has done great honour to Italian medical science

PROFESSIONAL CLASSES WAR RELIEF COUNCIL—The annual meeting of this council was held on June 9th Although some departments of this excellent work have been closed down, the Council is keeping on certain of its activities until next year at its new offices at 251, Brompton road, S W The report for 1919 shows that over £6000 was spent on education the average number of families per term receiving assistance being 150 The training of young people for the professions was continued New applications to the number of 566 were dealt with in the General Assistance Department The total sum disbursed in all departments was nearly £15 000

The Services.

ARMY MEDICAL SERVICE

Major and Bt Lieut Col R B Ainsworth to be temporary Assistant Director General vice Major (temp Lieut Col) A B Smallman

Capts G H Latham and G McK Thomas are transferred to the unemployed list

Parliamentary Intelligence.

HOUSE OF LORDS.

THURSDAY, JUNE 17TH.

Census Bill.

THE Census Bill was read a third time.

HOUSE OF COMMONS.

TUESDAY, JUNE 15TH.

Small-pox in Glasgow.

Mr. **NEIL MACLEAN** asked the Secretary for Scotland whether any of the cases removed to hospital as suffering from small-pox during the present outbreak in Glasgow had been vaccinated at any time during the past six months; and what were the ages of the cases, how many were vaccinated cases, how many unvaccinated, and in how many was the question of vaccination doubtful.—Mr. **MUNRO** (Secretary for Scotland) replied: 1. No cases have been removed to hospital who had been vaccinated within six months previous to the date of contracting infection. Twenty-nine persons who subsequently developed small-pox were vaccinated either in their own homes or in the reception houses after known exposure to infection—that is, between the date of contracting infection and the development of the disease. In 7 of these cases vaccination failed. In 22 the disease was in a modified form, except in the case of a child of 2 months, who had been exposed to infection at home for seven days before discovery and vaccination. 2. 186 cases of all ages have been vaccinated in infancy. The mortality among these has been 12 per cent. 168 of these cases and the whole of the deaths have occurred among persons over 16 years of age. 3. In 57 cases who had never been vaccinated the mortality has been 35 per cent., all but 6 being under the age of 15. 4. In 3 cases the primary vaccination was doubtful. One of these, an adult, died. These are included in the 186 vaccinated cases. Of the 186 previously vaccinated cases, 1 had been revaccinated in 1890, 5 in 1901, 1 in 1906, and 1 in 1916, but the two latter showed no evidence of successful revaccination. Among the group vaccinated in infancy only four were under 10 years and were mild and modified cases.

WEDNESDAY, JUNE 16TH.

National Hospital for the Paralysed and Epileptic.

Mr. **L'ESTRANGE MALONE** asked the Minister of Health whether he was aware that, owing to the financial position, the National Hospital for the Paralysed and Epileptic in Queen-square, W.C., was closing; whether he was aware that many other hospitals in London were in a similar condition; that many of these hospitals were making appeals to charity and displaying such notices as "Help us to keep open"; and whether, in view of the professed objects of the Ministry of Health and the repeated declarations of the Prime Minister and others concerning the new social conditions proposed to be introduced by the Coalition Government, he would consider the desirability of giving immediate State aid to such hospitals, which had hitherto relied on charity, or, alternatively, to nationalise the medical services, as had been successfully accomplished in Russia with considerable benefits to the working classes.—Dr. **ADDISON** replied: I am aware that the hospital in question and two other hospitals in London are contemplating closing in whole or in part, and the question of giving interim assistance to hospitals in serious financial difficulties is under consideration by the King's Fund. The position of many other London hospitals gives ground for anxiety, and I am considering what measures can be taken to meet the situation without prejudicing the voluntary principle and without losing the services of the voluntary workers, to whose coöperation I attach the greatest value. I have never been in favour of nationalising the voluntary hospitals, and the information available as to the sanitary condition of Russia has not led me to modify my views on this point.—Mr. **MALONE**: Would not the £3,000,000 being spent on tawdry finery by the War Office be better spent if it were appropriated to the hospitals?—Dr. **ADDISON**: That does not affect the question of the existence of the voluntary hospitals.

Tropical Diseases Hospital, Bath.

Mr. **WIGNALL** asked the First Commissioner of Works whether he was aware that the delay in the erection of huts at the Ministry of Pensions Hospital, Bath, for the accommodation of pensioners suffering from tropical diseases was causing inconvenience to the medical staff and unnecessary suffering to the men; whether he was aware that the huts, or sections of them, were delivered months ago; and whether he would take the necessary steps to have the huts erected without delay.—Sir A. **MOND** (First Commissioner of Works) replied: The huts in question were originally required for the accommodation of nurses who have since been housed elsewhere. It is now proposed, when funds are available, to utilise the huts for additional ward accommodation.—Mr. **WIGNALL**: Is the right honourable gentleman aware that all the arrangements are made for the reception of these sufferers, and that when the report came up last week complaining of the delay in completing the work, a strong resolution was passed?—Sir A. **MOND**: I am not aware of those facts. All that I know is the Ministry of Pensions have given the reply which I have just read.

THURSDAY, JUNE 17TH.

Hospital Accommodation for Neurological Cases.

Sir **HENRY HARRIS** asked the Minister of Pensions whether he was aware that there were more than 400 cases of men awaiting in-patient neurological treatment in London and the region immediately surrounding it; and whether, in view of the very serious results of delay and neglect in such cases he could state what steps the Ministry had taken to provide the additional accommodation required.—Mr. **MACPHERSON** replied: The number stated is approximately the number of cases awaiting treatment for the whole area covered by London and the eastern and south-eastern counties. Every effort is being made to obtain further hospital accommodation. There are many difficulties to overcome, but I hope that additional facilities may be available at an early date.

War Pensions Bill and Dependents' Appeals.

Mr. **HURD** asked the Minister of Pensions whether he had received representations from local pensions committees strongly urging that provision should be made in the War Pensions Bill to give a dependent the same right of appeal against refusal of pension on the grounds that the man's death was not due to or aggravated by service as was conceded to widows and children, and that Section 8 of the War Pensions (Administrative Provisions) Act, 1919, be extended to dependents; and whether, seeing that this concession, while throwing no undue pressure on the tribunal, would meet cases of considerable hardship which had been brought to the notice of the council of the association of local war pensions committees, he would say what action he proposed to take in this direction.—Mr. **MACPHERSON** replied: The answer to the first part of the question is in the affirmative. The proposal in the second part of the question will come up for consideration on the War Pensions Bill, which stands referred to a Committee. Perhaps my honourable friend will await the discussion upon it.

Alternative Pensions for Nurses.

Mr. **LEONARD LYLE** asked the Minister of Pensions whether alternative pensions were allowed to officers and not to nurses; whether these pensions permitted officers to be placed in the same financial position as they enjoyed before the war, plus an increase; if they were thereby benefited more than by the pensions ordinarily laid down, while nurses were not allowed to so benefit; and whether, in view of the feeling amongst nurses generally, he would reconsider the distinction with a view to a change being made.—Mr. **MACPHERSON**: Alternative pensions have not hitherto been allowed for nurses by the Royal Pension Warrants. The question of extending the benefits of this class of pension to nurses is at present under consideration, but I am not yet in a position to make any announcement.

Medical Re-examinations for Disability Pensions.

Captain **COOTE** asked the Minister of Pensions whether he was aware of the distress caused to disabled men by the long intervals which elapsed between the expiration of a period for which a pension was granted and their appearance before a medical board for further examination; that this distress was intensified by the delay in the re-issue of pension if such was recommended by the medical board and subsequently confirmed; and whether he would issue instructions that a medical board should give the man in such cases written announcement of their finding upon which he would be able to draw an advance of pension from his local committee.—Mr. **MACPHERSON**: It is the practice at present to arrange for medical re-examination of the men six or eight weeks in advance of the expiration of the current awards, and in any cases where the circumstances are such that a medical re-examination cannot be arranged in time to prevent an interruption of the pension arrangements are at once made to continue the expiring pension. Delay should not therefore occur. While I do not think that the proposal made by my honourable and gallant friend in the last part of his question is advisable, I am considering how best to meet any difficulty which may arise.

The Blind Welfare Committee.

Mr. **SEXTON** asked the Minister of Health whether, in view of the fact that the committee to consider the prevention of blindness was not to be composed entirely of experts, he would arrange for a representative of the National League of the Blind to serve on the committee, in view of the knowledge as to working class conditions such representative could bring to the deliberations of the committee —Dr ADDISON replied I am anxious not to increase the number of this committee unnecessarily Its deliberations will extend to various kinds of industrial occupations, and it will no doubt seek the assistance of those competent to speak as regards the conditions obtaining in these occupations so far as they come within the scope of the inquiry, and I have already decided to ask a representative of the trade unions to serve on the committee

Small pox in Glasgow

Mr ROBERT YOUNG asked the Secretary for Scotland whether he would draw the attention of the Scottish Ministry of Health to the fact that recent outbreaks of small pox in London, Liverpool, and other English towns had been limited to a few persons through the energetic action of the health officials of those towns and whether he would suggest to the Scottish Board of Health that they should make representations to the health officials of the city of Glasgow to the effect that the method so advantageously adopted in English cities should be followed in Glasgow at the present time, and in any future outbreak, in order that such outbreaks might not spread as the present outbreak had been allowed to spread —Mr MORISON (Lord Advocate) replied My right honourable friend is not aware that the measures taken in English towns for the control of outbreaks of small pox have been more efficient than those taken in Glasgow The Scottish Board of Health have from the beginning of the outbreak been in daily touch with the public health officials of Glasgow, and are satisfied with the measures taken to deal with the outbreak and to prevent the further spread of the disease later in the season Adequate arrangements have been made from the start for the hospital accommodation of cases, for the isolation of contacts and for the free vaccination of the general public

Employment of Women Before and After Childbirth

Mr ROBERT RICHARDSON asked the Secretary for the Home Department if he could state when it was proposed to introduce the Bill to give legislative sanction to the proposals regarding the employment of women before and after childbirth which were adopted at the Washington International Labour Conference —Dr ADDISON (Minister of Health) replied I have been asked to answer this question The British Official Representatives at the Washington Conference refrained from voting on this question The extent to which the British Government shall adhere to the recommendations of the Conference is at present under consideration The matters involved largely affect insurance questions, and they are now being carefully examined

Medical Fees in Workmen's Compensation Cases

Sir HERBERT NIELD asked the Secretary for the Home Department whether, seeing that the compensation payable under the Workmen's Compensation Act, 1906, had been considerably increased he would reconsider the scale of fees prescribed for, and payable to, medical referees and assessors appointed by the Secretary of State for services rendered under the Act, having regard to the fact that such fees, when prescribed, were upon an exceedingly low scale, the responsibility of the work, and especially in view of the present increased awards to applicants and the reduced value of the fees and taking into consideration that the medical fees under the National Insurance Act had been augmented consequent upon the increased cost of living —Mr SHORTT replied This question will be considered with due regard to all relevant circumstances after the Departmental Committee which has been inquiring into the working of the Workmen's Compensation Act, has reported

Threatened Invasion of Zymotic Disease

The House went into Committee on a Vote not exceeding £1 279 379 for expenses in connexion with embassies, missions, and consular establishments abroad and other expenditure chargeable to the Consular Vote

Mr BALFOUR (Lord President of the Council), in the course of a statement on the League of Nations, referred to the attempt to deal with the threatened invasion of zymotic disease from the East to the West, especially in Poland Typhus had raged both in Russia and in Poland, and our leading medical authorities were seriously alarmed as to what was going to happen in Central Europe in the coming winter They had done their best in the matter, they had acted through the Red Cross Societies and in addition, they had appealed to the nations forming the Union to provide such funds as were necessary for staying the plague The Polish Government by all accounts had spent money freely and with great public spirit and skill in the matter, but the common opinion was that their efforts were not sufficient, and it would be unfair to throw upon them the whole burden of acting as guardians of the health of the West without the West doing something to aid them in this all important task According to their experts £2,000,000 would be sufficient to slay the evil, and of that sum an immediate expenditure of £250 000 would be obligatory, or at all events of the greatest importance, if the best results were to be got Their appeal to the nations would be an appeal to their generosity, and he refused to doubt that when the appeal was made by the League of Nations to its component members it would receive an adequate response

FRIDAY, JUNE 18TH

Financial Position of London Hospital

Mr A T DAVIES asked the Minister of Health whether his attention had been directed to the financial position of the London Hospital, whether he was aware that Lord Knutsford, as chairman of the institution, announced that there were only sufficient funds in hand to pay the bills for eight weeks, and whether, in view of the financial straits to which this and similar institutions were reduced, the Ministry of Health would at once consider the question of assistance, especially in the poorer districts of the metropolis —Dr ADDISON replied I am fully aware of the position of the London Hospital, and I am considering what steps can be taken to assist this and other hospitals similarly circumstanced without prejudicing the voluntary principle

MONDAY, JUNE 21ST

Dentistry Bill

Viscount ELVEDEN asked the Minister of Health whether it was proposed to introduce legislation this session to carry out the recommendations of the Departmental Committee on Dentistry which reported in February, 1919 —Dr ADDISON replied Yes, Sir A Bill is now in course of preparation

Cost of the National Insurance Act

Lieutenant Colonel CROFT asked the Lord Privy Seal if he could now state what was the total cost of the National Health Insurance Act since its inception, and what had been the amounts paid for administration and in benefits respectively —Mr BONAR LAW replied The total cost of National Health Insurance from its inception to Dec 31st, 1919, was (as respects England and Wales) in round figures £162,000,000—namely contributions of employers and employed, £119 000 000, Exchequer grants, £43,000 000 The amounts paid for administration and benefits were £21,000,000 and £84 000,000 respectively For Ireland the total cost was in round figures £7,700,000—namely, contributions of employers and employed £5,200 000, Exchequer grants, £2,500 000 The amounts paid for administration and benefits were £1,500,000 and £3,700 000 respectively I have not yet received the figures for Scotland

TUESDAY, JUNE 22ND

Special Schools for Defectives

Major HILLS asked the President of the Board of Education if he would tell the House what progress had been made in the provision of special schools for physically defective and epileptic children under the Education Act, 1918 —Mr FISHER replied On July 31st, 1914, the number of special schools for physically defective and epileptic children was 102 At the present moment it is 171 In addition, the Board have under consideration upwards of 60 proposals from local education authorities and a few from voluntary bodies for the establishment of special schools, of which the greater number are open air schools for physically defective children

Remuneration of Part time Prison Medical Officers

Captain ELLIOT asked the Secretary of State for the Home Department if he would state what steps, if any, were being taken to improve the remuneration of part time prison medical officers, as these had received neither increase of salary nor bonus since the outbreak of the great war —Mr SHORTT replied The Treasury have now sanctioned an increase of these officers' remuneration, which, I hope, will prove satisfactory

URBAN VITAL STATISTICS

(Week ended June 19th, 1920)

English and Welsh Towns —In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 18 million persons, the annual rate of mortality, which had been 12 8, 11 6, and 11 1 in the three preceding weeks further fell to 10 6 per 1000 In London, with a population of nearly 4½ million persons, the annual death rate was 10 0, or 0 6 per 1000 below that recorded in the previous week, while among the remaining towns the rates ranged from 4 3 in Ealing 4 9 in Walthamstow, and 5 4 in Eastbourne to 16 9 in Blackpool 17 0 in Carlisle, and 19 0 in Bootle The principal epidemic diseases caused 236 deaths, which corresponded to an annual rate of 0 7 per 1000, and comprised 73 from infantile diarrhœa, 64 from measles, 46 from diphtheria 42 from whooping cough, 6 from scarlet fever, and 5 from enteric fever Measles caused a death rate of 1 8 in Leicester and in Wigan, 2·0 in Aberdare, and 2 4 in Newport (Mon) The deaths from influenza, which had declined from 216 to 86 in the five preceding weeks, further fell to 65, and included 14 in

Sheffield, 7 in London, and 4 in Manchester. There were 1705 cases of diphtheria, 1654 of scarlet fever, and 5 of small-pox under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 1722, 1642, and 4 respectively at the end of the previous week. The causes of 26 of the 3629 deaths in the 96 towns were uncertified, of which 7 were registered in Birmingham, 3 each in Stoke-on-Trent and Gateshead, and 2 in Liverpool.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2¼ million persons, the annual rate of mortality, which had declined from 18·4 to 12·7 in the six preceding weeks, rose to 13·3 per 1000. The 309 deaths in Glasgow corresponded to an annual rate of 14·5 per 1000, and included 11 from measles, 8 from infantile diarrhœa, 2 from diphtheria, and 1 each from small-pox and whooping-cough. The 73 deaths in Edinburgh were equal to a rate of 11·2 per 1000, and included 3 fatal cases of diphtheria.

Irish Towns.—The 136 deaths in Dublin corresponded to an annual rate of 17·1, or 0·9 per 1000 above that recorded in the previous week, and included 7 from whooping-cough, 4 from infantile diarrhœa, and 1 from diphtheria. The 112 deaths in Belfast were equal to a rate of 14·1 per 1000, and included 3 from infantile diarrhœa, and 1 each from measles, diphtheria, and whooping-cough.

Appointments.

Pedley, C. F., M.R.C.S., L.R.C.P. Lond., has been appointed Resident Medical Officer at Winsley Sanatorium, Wilts.

Prentice, A., M.B., Ch.B. Edin., Honorary Anæsthetist to the Metropolitan Ear, Nose, and Throat Hospital.

Saі, P., M.B., B.S. Lond., M.R.C.S., L.R.C.P. Lond., Director of Siriraj Hospital, Bangkok.

Williams, S., M.D. Lond., Medical Referee under the Workmen's Compensation Act, 1906, for County Court Circuit No. 31.

Certifying Surgeons under the Factory and Workshop Acts: Gunn, J. T., M.B., Ch.B. Edin., F.R.C.S. Edin. (Blackford); Lilley, E. L., M.R.C.S., L.R.C.P. Lond. (Leicester, West); Brown, J. P., M.B., C.M. Glasg. (Campbeltown).

Vacancies.

For further information refer to the advertisement columns.

Aberdeen, Rowett Research Institute in Animal Nutrition.—Physiologist. £400.

Bath, Royal United Hospital.—Res. M.O. £150.

Battersea General Hospital (Incorporated), Battersea Park, S.W.—Res. M.O. £200.

Belgrave Hospital for Children, Clapham-road, S.W.—H.S. £100.

Birmingham Children's Hospital.—Hon. Dent. S. Also Two Visiting Anæsth. and Jun. Anæsth., £75 and £50 respectively. Also Res. M.O. £150.

Birmingham General Hospital.—H.S.'s and H.P. Also Res. M.O. £155.

Bloemfontein (O.F.S.), South Africa, Municipality.—M.O.H. £800.

Bolingbroke Hospital, Wandsworth Common.—H.S. £150.

Bolton Infirmary and Dispensary.—Female Second H.S. £250.

Bradford, Odsal Sanatorium.—Res. M.O. £350.

Bradford Royal Infirmary.—Res. Surg. O. £250.

Brighton, Royal Alexandra Hospital for Sick Children.—H.S. £100.

Brighton, Royal Sussex County Hospital.—Jun. H.S. £130.

Bristol General Hospital.—Cas. H.S. £175.

Burnley, Victoria Hospital.—H.S. £250.

Canning Town Women's Settlement Hospital, Balaam-street, Plaistow, E.—Female Hon. Asst. P. Also Female Res. M.O. £150.

Central London Throat and Ear Hospital, Gray's Inn-road.—Hon. Asst. Anæsth.

Chichester, Royal West Sussex Hospital.—H.S. £200.

Colchester, Essex County Hospital.—H.P. £200.

Coventry Education Committee.—School Dentists. £400.

Croydon County Borough.—Female Asst. M.O.H. for Maternity and Child Welfare Work. £500.

Croydon General Hospital.—Jun. H.S. £150.

Dorset County Council.—Asst. County M.O. £500.

Dreadnought Hospital, Greenwich.—H.P. £100.

Dumfries and Galloway Royal Infirmary.—Res. H.S. £150.

East Suffolk County Education Committee.—Dental Surgeon. £500. Asst. School M.O.'s. £500.

Federated Malay States.—Radiologist. £840–£980.

Fulham Infirmary, St. Dunstan's-road, Hammersmith, W.—Third Asst. M.O. £300.

Galway, University College.—Prof. of Anat. £658.

Glasgow University.—Lectureship in Ophthalmology.

Gloucester County Asylum.—Jun. Asst. M.O. £300.

Gloucester, Gloucestershire Royal Infirmary and Eye Institution.—H.P. £175.

Hammersmith Parish.—District M.O. and Pub. Vac. £130.

Hendon Urban District Council.—M.O.H. £750.

Holt, Norfolk, Kelling Sanatorium.—Asst. Res. M.O. £450.

Hospital for Sick Children, Great Ormond-street, W.C.—Cas. M.O. £200. Also Med. Reg. and Path. £200.

Huddersfield Royal Infirmary.—Sen. H.S. £250.

Hull Royal Infirmary.—Asst. H.S. £150.

Isle of Ely County Council.—Clin. Tuberc. O. and Asst. M.O.H. and Sch. M.O. £500.

Johannesburg, South African School of Mines, &c.—Professor of Pharm. £1000.

King's College Hospital, Denmark Hill, S.E., Department of Dermatology.—Jun. P.

Leamington Spa, Warneford, Leamington, and South Warwickshire General Hospital.—Res. H.P. £200.

Leeds City.—Female Asst. M.O. for Maternity and Child Welfare. £500.

Leeds City Tuberculosis Sanatorium.—Res. Asst. M.O. £300.

Leeds Public Dispensary.—Res. M.O. £200.

Leicester Royal Infirmary.—Two H.S.'s £200.

Liverpool Stanley Hospital.—Res. P. and S. £150.

London County Mental Hospital Service.—Sixth and Seventh Asst. M.O.'s. £300.

London Jewish Hospital, Stepney Green, E.—Hon. P. in Charge of X Ray Dept.

Manchester, Ancoats Hospital.—H.P. £150. Also Two Jun. H.S.'s. £100.

Manchester, Baguley Sanatorium for Tuberculosis.—Third Asst. Res. M.O. £300.

Manchester Royal Infirmary, Roby-street.—Second Res. M.O. £100. Also H.S.'s. £50 first six months, £100 second.

Manchester University.—Lecturer in Anatomy. £500.

Middlesbrough Education Committee.—Sch. Dent. £400.

Miller General Hospital for South-East London, Greenwich, S.E.—Res. Cas. O. £150. Also H.S. £100. Also Orthopædic S. and Hon. P.

Newcastle-upon-Tyne, Hospital for Sick Children.—Sen. and Jun. Res. M.O.'s. £250 and £200 respectively.

Norwich City.—Asst. School M.O. and Asst. M.O.H. £560.

Portsmouth County Borough.—Asst. M.O.H. and Chief Tuberc. O. £500.

Prince of Wales's General Hospital, Tottenham, N.—Jun. H.P. £120. Also Hon. Asst. S.

Queen Mary's Hospital for the East End.—Hon. Dent. S.

Reading Education Committee.—Sen. Asst. School M.O. and Asst. to M.O.H. £600. Asst. School M.O. and Asst. to M.O.H. (Female). £500.

Rhondda Urban District Council.—Asst. School M.O. and M.O.H. £600.

Rotherham Hospital.—Jun. H.S. £150.

Royal Free Hospital, Gray's Inn-road, W.C.—H.P. and Second H.P. and Anæsth. £50 each. Also Hon. Anæsth. and Asst. S.'s.

Royal Westminster Ophthalmic Hospital, King William-street, West Strand, W.C.—Refractionist Assts. £100.

Rugby, Hospital of St. Cross.—Female Res. M.O. £200.

Ryde, Royal Isle of Wight County Hospital.—Res. M.O. £250.

St. Helens Education Committee.—Dentist. £450.

St. Mark's Hospital for Cancer, Fistula, and Other Diseases of the Rectum, City-road, E.C.—Hon. S. and Hon. Asst. S. Also H.S. £150.

St. Thomas's Hospital.—Asst. Radiologist. £500.

Salisbury General Infirmary.—H.S. and Asst. H.S. £200 and £150.

Seamen's Hospital, Albert Dock, Connaught-road, E.—H.S. £100.

Sheffield Royal Hospital.—Asst. Cas. O. £150.

Sheffield Royal Infirmary.—H.P. £150.

Southampton County Borough.—Asst. M.O.H. £600.

Stafford, Staffordshire General Infirmary.—H.S. £250.

West London Hospital, Hammersmith, W.—Asst. S.

Wigan Infirmary.—Hon. S., P., Asst. S., and Asst. P. Also Senior H.S. £250.

Wolverhampton and Staffordshire General Hospital.—H.S. £200.

Worcestershire County Council.—Asst. County M.O.'s and Sch. Oculist. £500 each.

The Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Stokesley and at Truro.

The Home Secretary gives notice of a vacancy for an additional Referee under the Workmen's Compenation Act for Circuit No. 31 (Neath and Aberavon County Courts). Applications should be made to the Private Secretary, Home Office, not later than July 14th.

Births, Marriages, and Deaths.

BIRTHS.

Clive Matthews.—On June 14th, at Eversfield-place, St. Leonards-on-Sea, the wife of L. Clive Matthews, L.D.S. R.C.S.E., of a son.

Cooke.—On Sunday, June 20th, at 59, London-road, Horsham, the wife of Clement Cooke, M.D. Lond., of a daughter.

Holman.—On June 21st, at Avenue-road, N.W., the wife of Frank Kay Holman, M.D., of a daughter.

Holmes.—On June 16th, at Harley-street, W., the wife of Gordon Holmes, M.D., F.R.C.P., C.M.G., C.B.E., of a daughter.

Kidman Bird.—On May 29th, at "Cooksditch," Faversham, Kent, the wife of M. W. Kidman Bird, F.R.C.S., of a son.

Phillips.—On the 18th June, at 2, Cavendish Court, Cavendish-square, W. 1, to Phyllis, wife of Hugh R. Phillips, M.D.—a son.

Tyrrell Gray.—On 12th June, at 28, Harley-street, W. 1, the wife of H. Tyrrell Gray, F.R.C.S., of a son.

MARRIAGES.

Haswell—Meek.—On June 14th, at Forest Church, Langdon Beck, Durham, William Cyril Haswell, M.B., to Evelyn Phebe, third daughter of J. M. Meek, M.A., of Coatham, Redcar.

James—Clarke.—On 21st June, at All Souls, Langham-place, Dr. Vincent C. James, son of Dr. and Mrs. Coram James, 114, Walm-lane, Cricklewood, to Mildred Ivy, widow of the late Lieut. Richard H. Clarke, M.C., of Liverpool.

McCarter—Jamison.—On June 3rd, at Rasharkin Presbyterian Church, William Harold Raphael McCarter, M.B., to Margaret Wallace, daughter of Revd. W. J. and Mrs. Jamison, The Bridge House, Kilrea.

DEATHS.

Inman.—On June 17th, suddenly, at Eglinton Park, Kingstown, Colonel A. W. P. Inman, late Army Medical Service, aged 65.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS
Monday, June 28th

ODONTOLOGY (Hon Secretaries—G Paton Pollitt, W Kelsey Fry, J Howard Mummery) at 8 P M

• *Discussion*

On "The Pathology of Dental Cysts, to be opened by Mr J G Turner, F R C S

The following Fellows and Members have promised to take part in the discussion —Mr F Colman, Mr E D D Davies Mr Dolamore, Mr F N Doubleday Mr M F Hopson, Mr B Hughes, Mr T B Layton, and Mr Herbert Tilley

SEAMEN S HOSPITAL SOCIETY, *at the London School of* Tropical Medicine, Endsleigh gardens N W

MONDAY, *June 28th —2* P M, *Lecture —Sir Leonard Rogers* Leprosy.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST GRADUATE MEDICAL ASSOCIATION, in the Barnes Hall, Royal Society of Medicine, 1, Wimpole street, W (by permission of the Royal Society of Medicine)

Short Film Demonstrations illustrating Post Graduate Teaching in Medicine, Surgery and its Specialties will be given on June 29th, July 1st, 5th, 9th, and 12th, by the Fellowship of Medicine, in conjunction with the British Film Institute

TUESDAY, June 29th —5 30 P M, (1) Dr Fred H Albee Bone Graft (Inlay), Replacing Portion of Humerus (2) Dr Howard A Kelly Hysterectomy for Pyosalpinx (3) Dr Charles A Elsburg Laminectomy (Tumour of Spinal Cord)

THURSDAY —5 30 P M, (1) Major H C Marble Approved Methods Splints and Appliances for the Treatment of Bone and Joint Injuries (2) Dr Edward L Keyes, jun Radical Cure of Undescended Testes (3) Dr A Berger Repair of Fracture of Jaw

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION, 11, Chandos street, Cavendish square, W

MONDAY, *June 28th —5 15* P M, *Lecture —Mr R W Tustin* Milk Supply (illustrated by the kinematograph and lantern slides)

LONDON HOSPITAL MEDICAL COLLEGE (SURGICAL UNIT), in the Units Lecture Theatre, London Hospital, E

Special Course of Lectures open to both Students and Post Graduates

Three Lectures on The Acute Abdomen—

WEDNESDAY, June 30th —4 P M, Mr R Howard (Lecture III)

WEST LONDON POST GRADUATE COLLEGE, West London Hospital, Hammersmith, W

MONDAY, June 28th —2 P M, Dr Simson Diseases of Women 2 P M, Mr B Harman Eye Department

TUESDAY —10 A M, Dr Robinson Gynæcological Operations 2 P M, Mr Banks Davis Diseases of the Throat, Nose, and Ear

WEDNESDAY —2 P M, Dr Owen Medical Out-patients 2 P M, Mr Addison Operations

THURSDAY —2 P M Mr D Armour Operations 2 20 P M, Dr A Saunders Visit to Medical Wards

FRIDAY —2 30 P M, Mr T Gray Operations 2 30 P M, Mr Addison Visit to Surgical Wards

SATURDAY —2 P M, Dr Beddard Visit to Medical Wards

Daily —10 A M, Ward Visits 2 P M, (June) In patient and Out patient Clinics and Operations, (July) In patient Clinics and Operations

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen square, W C 1

MEDICAL SCHOOL

MONDAY, June 28th —2-3 30 P M, *Out-patient Clinic Dr Collier* 3.30 P M, Dr Saunders Compression Paraplegia

TUESDAY, June 29th —2-3 30 P M, *Out-patient Clinic Dr* Grainger Stewart 3 30 P M, Dr Risien Russell Progressive Muscular Atrophy

WEDNESDAY, June 30th —2 P M, Dr James Taylor Ocular and Visual Conditions in Nervous Disease 3 15 P M, *Dr Gordon* Holmes Cerebro spinal Syphilis

THURSDAY, July 1st —2-3 30 P M, Out-patient Clinic Dr Farquhar Buzzard 3 30 P M, Dr Gordon Holmes Cerebro-spinal Syphilis

FRIDAY, July 2nd —2-3 30 P M, Out-patient Clinic Dr Gordon Holmes. 3.30 P M, Dr Collier Demonstration of Ward Cases

Fee for Post-Graduate Course £7 7*s* C M HINDS HOWELL, Dean

TIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland-street, W

MONDAY, June 28th —5 30 P M, Post-Graduate Lecture —Dr. Hamill High Blood Pressure

ING S COLLEGE HOSPITAL MEDICAL SCHOOL (UNIVERSITY OF LONDON)

A Course of Post-Graduate Lectures on Syphilis is being given by various members of the staff of King s College Hospital during the present year

FRIDAY, July 2nd —9 15 P M, *Prof A Whitfield* Treatment of Syphilis II *(Concluding Lecture)*

ALE LOCK HOSPITAL Dean street, W

MONDAY, June 28th, WEDNESDAY, AND FRIDAY —5 P M, Dr C Russ Demonstration of the Treatment of Gonorrhœa by Electrolysis

NORTH EAST LONDON POST GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N

MONDAY, June 28th —2 30 P M, Mr J B Banister Gynæcological

TUESDAY —9 45 A M, Lieut Col R H Elliot Selected Eye Cases and Operations 2 15 P M, Selected Cases —Mr E Gillespie Congenital Dilatation of the Colon 3 15 P M, Clinical Lecture —Dr A J Whiting Sinus Irregularity of the Heart 4 30 P M, Dr J B Banister The Present Position of the Treatment of Ante partum Hæmorrhage

WEDNESDAY —2 30 P M, Dr W J Oliver Dermatological

THURSDAY —2 30 P M, Mr N Fleming Ophthalmological Dr J Metcalfe Radiology

FRIDAY —2 30 P M, Dr C E Sundell Diseases of Children

SATURDAY —3 P M, Mr H W Carson Selected Surgical Cases

Daily —2 30 P M, Operations Medical and Surgical Clinics, &c

DEATH OF A TRANSVAAL DOCTOR —Dr. H. Scott Russell, a highly esteemed citizen of Klerksdorf, Transvaal, died on April 30th from double pneumonia, having been ill only seven days Dr. Russell had practised in Klerksdorf for over a quarter of a century, and was a member of many public bodies, chief of the local Caledonian Society, and a prominent Freemason He was once a municipal councillor, and was well known as a public benefactor and a friend of the poor

Notes, Short Comments, and Answers to Correspondents.

SOLUBLE LEAD IN CASSEROLES.

BY HELEN MASTERS, B.SC.,
HOUSEHOLD AND SOCIAL SCIENCE DEPARTMENT, KING'S COLLEGE FOR WOMEN.

ATTENTION has already been drawn in the columns of THE LANCET[1] to the fact that casseroles made of glazed pottery ware sometimes yield appreciable amounts of soluble lead when treated with dilute solutions of organic acids. At the time when the former observations were made casseroles were rather a scarce commodity and those obtainable were chiefly of French make. During the last few months, however, casseroles have been coming on to the market in increasing number and variety, and as the presence of soluble lead in these vessels appears to be of some importance from the point of view of public health, further experiments have been made and specimens of several different makes of casserole examined.

In this country there is no standard test for the examination of glazed ware in the finished condition, but in Germany the official test is made by boiling a 4 per cent. solution of acetic acid in the vessel for half an hour; the sale of cooking utensils which yield any lead when thus treated is prohibited. In actual practice acetic acid is used for cooking purposes chiefly in the form of vinegar, and then, in this country at any rate, usually only in small quantities; whereas citric acid and also malic acid occur in a number of different fruits and vegetables which are often cooked in casseroles.

The acidity of a number of fruit juices is given by Leach[2] and expressed as citric acid; this acidity varies from 0·5 to 5·0 per cent. On this basis it was thought that if the test were made with a 1 per cent. solution of citric acid instead of with a 4 per cent. solution of acetic acid, the conditions would approximate more closely to those met with in practice. Some previous observations made with the two acids showed that the amount of lead extracted with 1 per cent. citric acid was greater than that extracted with 4 per cent. acetic acid. A few experiments made with malic acid gave results similar to those obtained with citric acid.

The Experiments Described.

The vessels examined were made of pottery ware, in some cases glazed on the inside only, and in others glazed both inside and out. Experiments had previously been made with casseroles of fireproof china, and these were found to be lead-free.[3] The casserole was nearly filled with a measured volume of the acid solution, just sufficient margin being allowed for boiling. Under these conditions it was assumed that the whole of the internal surface of the vessel would come into contact with the acid, and the area thus exposed was calculated from the internal dimensions of the vessel. The casserole was covered with its lid and the solution was brought to the boil, and allowed to boil gently for half an hour. The amount of lead in the solution was then determined colorimetrically by precipitation as sulphide. If no coloration, or only a very slight coloration was observed when a portion of the solution was tested, the solution was concentrated to a small volume and again tested.[4]

Control experiments were made from time to time to ensure that the citric acid solution was lead-free. In one or two cases where the amount of lead yielded was considerable, the lead was also determined gravimetrically, by precipitation as sulphate, and this method gave results which confirmed those obtained colorimetrically.

The Results Discussed.

The results have been expressed as milligrammes of lead monoxide per square decimetre of the glaze, but in order that the amounts of lead extracted may be compared with the quantities found in contaminated waters, or other substances containing lead, the results are also given as parts of lead per 100,000 of the solution. The apparent discrepancy, suggested by a comparison of the two series of results, is entirely due to the fact that the vessels examined were not all of the same shape and varied from 100-1200 c.cm. in capacity; the ratio of the internal surface to the capacity is greater in the smaller vessels than in the larger. This ratio is also, to some extent, dependent on the shape of the vessel—i.e., the internal surfaces of two casseroles of the same capacity are not necessarily equal. The results are shown in Table I. Casseroles of the same make are indicated by the same initial letter. D and E were from the same makers, but D were glazed both inside and out, and E were glazed inside only; the glaze did not appear to be quite the same in the two cases.

TABLE I.

—	Mg of PbO per sq. dm of glazed surface.	Parts of lead per 100,000 of the solution.	—	Mg of PbO per sq. dm of glazed surface.	Parts of lead per 100,000 of the solution.

C_1	Trace	—	G_1	1·0	0·5
C_2	Nil.	Nil.	G_2	2·8	1·7

The results indicate that the use of a glaze containing lead in a more or less soluble form is widespread and is not confined to one country or to one make. Out of the 18 casseroles for which figures are given in the table, only 3—viz., C_1, C_2, and F—can be classified as free from soluble lead, and these were sold by the makers as "leadless glaze." This description suggests that some of the manufacturers are alive to the possible risks attached to the use of a lead glaze, but the fact that such a description is considered necessary might also be taken as further confirmation of the view that the use of a leadless glaze is the exception and not the rule.

There is considerable variation in the amount of lead extracted from different specimens of the same make of casserole. This may be partly due to faulty mixing of the glaze, but it is also probable that the resisting power of the glaze to the action of dilute acids is largely dependent on the temperature at which it is "fired," as well as on the uniformity of the surface and its freedom from small cracks or flaws. It is to be hoped that E_1, E_3, and E_4 are to be regarded as exceptions, and that normally the results obtained would approximate to those obtained with E_2. Two other casseroles of this make, E_5 and E_6, were used for the experiments described below. The results obtained with these vessels (see Table II.) are more in conformity with that obtained for E_2 than with those obtained for E_1, E_3, and E_4. On subsequent treatment with 1 per cent. citric acid E_6 gave 1·7 mg. of lead monoxide per square decimetre of glazed surface. E_5 cracked in the first experiment, so could not be further tested. On the other hand, it is only fair to state that E_4 was purchased at a different time from the other vessels of this class, and was not obtained from the same retailer, so that it seems unlikely that it came from the same batch as E_3 and E_1.

Even if results of the order obtained with the E_1, E_3, and E_4 are to be regarded as exceptional, there is no means of knowing when and how frequently such exceptions are likely to occur. At the time of writing other specimens of this make of casserole are not available, so this matter cannot be dealt with further at present. The glaze of E_1 showed marked colour changes after treatment with the acid solution, but these changes were not observed with E_3 and E_4, though the glaze in these cases presented rather a roughened appearance. As a general rule the appearance of the glaze was very little affected at first, but if the treatment was repeated several times the glaze to some extent lost its gloss and sometimes became slightly iridescent, but its appearance did not suggest that the casserole had been subjected to anything more than fair wear and tear.

The results given in Table I. are in all cases those obtained for the first treatment with the acid solution, but if the experiment is repeated several times it is found that, if an appreciable quantity of lead was extracted by the first treatment, it is also extracted by each of the subsequent treatments. Although in some cases the first two or three treatments may suggest that the amount of lead extracted is decreasing, the amount often increases again if the treatments are continued and, with the exception of those cases where the amount of lead at first extracted was very small, no indication was obtained that a stage would be reached when all the soluble lead would have been extracted. In the case of E_1 and E_3 the amount of lead extracted in the second treatment was even greater than in the first, but E_4 gave rather less.

Experiments with Fruit and Vegetables.

In order to obtain a more exact idea of the quantity of lead which might be extracted during cooking, a few experiments were made in which fruit and vegetables were cooked in the casseroles 100 g of the raw material were used for each experiment The cooked food was evaporated to dryness in a porcelain dish and, after the addition of sulphuric acid, ignited The sulphated ash was extracted with ammonium acetate and the lead in the filtrate determined colorimetrically A control experiment was made with the raw food material and all the reagents used in the test experiment As in this case the area of glazed surface exposed could not be readily calculated, the results are given as milligrammes of lead per 100 g , the raw material—and this also represents parts of lead—per 100,000 With the exception of E_1 the casseroles used in these experiments were new ones which had not received any previous treatment

[3] See Masters, The Analyst, May, 1919, p. 615.

[4] For further details of the method employed see "Applied Chemistry," Tinkler and Masters (Crosby Lockwood).

The Results Compared

In comparing the results of Table II with those of Table I it should be noted that the conditions in the two series of experiments are not identical *The acidity of the* fruit or vegetable is, in some cases, greater than that of the citric acid solution, but whereas in the first experiments the whole internal surface of the casserole was in contact with the acid solution, this was not the case when fruit or vegetable was used, a portion only of the surface, in some cases practically only the bottom of the vessel, was in contact with the food material in these experiments It would, of course, be possible nearly to fill the casserole with fruit or vegetable, and this is often done in practice, but for experimental purposes the difficulties attendant on evaporating and igniting a large bulk of food material had to be taken into consideration

TABLE II —*Lead Extracted from Casseroles by Fruit and Vegetables.*

Casserole	Fruit or vegetable 100 g	Acidity (as citric acid) per 100 g of raw material	Mg of lead extracted
A_6	Tomato	0 37	1 8
E_5	Lemon pulp and juice	2 0	0 75
E_6	Lemon juice	3 7	2 9
(E_1)	" "	3 7	25 0
A_7	" "	3 7	3 4
A_8	Rhubarb stalks	1 1	1 0
D_4	" "	1 1	1 5

If due allowance be made for these differences, the results given in Table II may be regarded as confirming those of Table I The variations observed in the amount of lead extracted from different specimens of the same make of casserole with citric acid are also shown with some of the casseroles in Table II

The actual amounts of lead extracted from the casseroles are not in themselves very great, but as water containing 1/10 gr. per gallon (= 0 14 parts per 100,000) or even 1/20 gr is stated to produce injurious effects,[6] the quantities of lead obtained in the experiments can hardly be regarded as negligible; the results demonstrate that the possibility of food cooked in these casseroles becoming contaminated with lead is by no means an unlikely one, especially when they are in regular use The regulations at present *in force with regard to the use of lead glaze* appear to be chiefly directed to safeguarding the worker who has to prepare and apply the glaze, and the possibility that the general public might suffer through its use on cooking utensils does not appear to have been sufficiently recognised In the interests of public health it would seem advisable that the use of a lead glaze for cooking utensils should be prohibited, but if this is not feasible, then, at any rate, a standard test might be adopted, to which the vessels could be submitted before coming on to the market

The Advantages of a Leadless Glaze for Cooking Apparatus

It might be suggested that the use of a leadless glaze would increase the cost of production, but a comparison of the retail prices charged for the casseroles used in the experiments showed that the leadless glaze casseroles worked out cheaper than the others For example, three casseroles were bought on the same day from the same retailer, the price of each casserole being 2*s* 6*d* The capacities of the vessels were as follows French casserole (A) = 750 c cm ; English casserole (E) = 650 c cm , leadless glaze casserole (C) = 1250 c cm The price charged for a French casserole having a capacity of 1250 c cm was 3*s* 3*d* The appearance and finish of the leadless glaze casseroles were not considered to be in any way inferior to those of the other makes Specimens of both C and F have been in use in the kitchens of the department for some months, and, so far, have given no cause for complaint

In the event of a standard test being adopted it would be advisable to insist that specimens of each batch should be examined, as single tests cannot be regarded as reliable, in any case this method of dealing with the difficulty should be regarded only as an unsatisfactory alternative to the compulsory use of a leadless glaze for all cooking ware

Amongst the latest additions to the materials used for cooking utensils is fireproof glass Specimens of two different makes of this glass have been examined and yielded no soluble lead when treated as described above The vessels were also tested as regards their powers of withstanding sudden changes of temperature and appeared to be satisfactory in this respect It seems possible that the housewife may find in the future, as the scientist has done in the past, that glass is capable of many modifications to suit a variety of different purposes

PUBLIC HEALTH IN JAMAICA.

THE population of Jamaica, as estimated for the year 1918, was 895 578, and the birth and death rates were 34 1 and 33 0 per 1000 respectively , the former ratio is exactly the same as for 1917 , the death ratio is considerably higher than in any of the preceding four years, during which it ranged between 20 4 in 1914 and 26 9 in 1917 , the marked increase in 1918 was due to influenza It is much to be regretted that 68 6 per cent of the births registered were illegitimate, and that "this phase of the country's life continues to show an upward and unsatisfactory tendency " For the fifth year in succession the record of the previous highest rate has been broken ; the lowest rate was in St Andrew's parish (60 12), while seven parishes had ratios over 70 per cent and Port Royal had 79 41 per cent The total number of illegitimate births was 20,990 The general death rate of 33 0 per 1000 was much exceeded in several parishes in St Andrew it was 43 6, in St Catherine 41 3, and in St Thomas 40 9, being in each case considerably higher than the birth rate , the small parish of Port Royal had the low ratio of 11 0 per 1000 Influenza caused 5038 deaths, in addition to 839 due to pneumonia consequent on the former disease , but it is considered by Mr David Balfour, the Registrar General, that the epidemic was responsible for a great many more deaths than were actually registered as having been caused thereby The chief fatal diseases (besides influenza) were fevers, not otherwise defined (5234), convulsions (2079), phthisis and pulmonary tuberculosis (1703), dropsy (1222), and "old age" (1829) It is, however, unfortunately the case that in 72 9 per cent *of the deaths registered during the year the causes were not medically certified*

HOSPITALS AND DISPENSARIES IN BENGAL

DURING 1918 there were 760 medical institutions of various kinds working under the Bengal Government, of which 22 were in the city of Calcutta At these latter hospitals and dispensaries the number of patients treated amounted to 439,806, of whom 34,703 were in patients , this shows an increase on the previous year in the number of in patients, due chiefly to influenza The total accommodation available was for 2438 patients, being an increase of 111 beds over that of the year preceding , but most of these were in temporary buildings improvised to meet the emergency of the influenza epidemic The superintendent of the Campbell Hospital points out (as is often recognised at home) that there is great need for some home or refuge for incurables, who use up *accommodation in the hospitals that would be more suitably* occupied by surgical patients and cases of acute disease More nurses are required, especially *at the Campbell Hospital* just mentioned, "*where the real nursing is done by students helped by ward coolies and other menials, supervised by the nurse in charge*" During *the influenza epidemic* 16,784 cases *were treated in the city hospitals , of* these 2777 were in patients, with 849 deaths Cholera also prevailed to some extent, 843 cases being admitted to hospital, of whom 207 died Sir Leonard Rogers's treatment is in use in all the hospitals, and the results are steadily improving Between February and September there was some plague in the city, 77 cases being treated in hospital, with 46 deaths

In Bengal, outside of Calcutta, as many as 6,368 171 persons received medical aid at the different hospitals and dispensaries (numbering 738), of which total 479,957 were treated in special hospitals for the police, public works, and other Government departments, railway hospitals, &c , and the remainder in various charitable institutions Nearly one third of these patients (1,877,753) *were cases of malaria,* being 258,514 more *than the number treated for this disease* in 1917 The number *of cases of influenza was* 134,057 , *of* these 1526 *were in patients, amongst* whom were 339 deaths Colonel J. K Close, I M S , who presents this report as *Officiating* Surgeon General with the Government of Bengal, summarises the financial position of the various hospitals and dispensaries and the structural improvements that have been or are in course of being undertaken The long-expected increase of pay for sub assistant surgeons was granted, with effect from June 1st last, the new scale being Rs 50 per month, rising to Rs 120 It is to be hoped that this will remedy a long-existing grievance It is gratifying to note the large sums provided by local subscriptions, especially the liberality of the Raja Roy Bahadur, of Lalgola, in support of the Berhampore Hospital, and of Raja Acharji Bahadur and other noblemen and gentlemen towards the Mymensingh Sadar Hospital rebuilding and extension fund. This liberality can only be described as princely.

WANTED, A HOME.

To the Editor of THE LANCET.

SIR,—A patient of mine, a lady, is suffering from disseminated sclerosis, she is practically confined to bed. Could any of your readers help me to find a home for her either in a nursing-home or in some doctor's or nurse's house? She can only pay 3 guineas a week. It must be in London. I am, Sir, yours faithfully,

M.D.

June 11th, 1920.

FOOD CONDITIONS IN AUSTRIA.

THE following interesting paragraph is taken from the *Economic Review* (June 16th):—

> Dr. Loewenfeld, an Austrian Secretary of State, has stated in the National Assembly that he hopes to be able to increase the rations, which for some time have been reduced, to their old level. The flour ration is to be increased immediately, and the bread ration in the near future. In any case, Austria may count upon an improvement in the conditions of existence. (*Neue Freie Presse*, May 15th.)

Hitherto we have heard little else than that famine conditions prevailed in Austria with a probable outlook of food deficiency diseases, and delegates were sent out from our scientific staffs, of which Dr. Harriette Chick was principal, with the view of pointing out the importance of including in the diet, as far as possible, accessory food factors. Humanity will welcome the relief that is promised in the above statement.

THE RANYARD NURSES.

THE nursing branch of the Ranyard Mission supplies nurses for the sick poor in their own homes in various parts of London, and according to the report for the year ending 1919 there were nursed during the year 395 maternity, 4430 medical, and 5617 surgical cases. The total number of visits paid by nurses was 221,198 and by sisters 5260. At minor ailment centres and dispensaries 211,916 visits were made, and the home visits to patients attending centres and dispensaries amounted to 1299. The society is supported by voluntary contributions, by grants from public bodies, and by local payments towards the cost of the nurses in the districts, but for the year under notice there is a deficit on the nurses' fund of £2800, largely due to a necessary increase in the salaries. The equipment and maintenance of a nurse costs roughly £140 a year. Subscriptions should be sent to Ranyard House, 25, Russell-square, W.C. 1, or to Lord Kinnaird, the treasurer, c/o Messrs. Barclay and Co., 1, Pall Mall East, London, S.W. 1.

DEMORALISATION BY KINEMA?

THE question of the kinematograph and its influence on the minds of children is brought to the fore by a case of the suicide of a 15-year-old boy at Ovingdean, near Brighton, the son of a coastguard. He was left in charge of the home and a little brother and sister, and on the parents' return he was found dead with a wound in the chest. He was nude except for a pair of pants and socks, and the big toe of the right foot was hitched in a piece of string attached to the trigger of a miniature rifle, which had been fastened to a chair, and on a paper were the words, "Good-bye all, Harry." No cause for suicide could be suggested, but the father said that his son went to the "pictures" every Saturday and that he read a good deal. The coroner, Mr. G. Vere Benson, said that he had come across cases in which boys had undoubtedly taken their own lives, either intentionally or accidentally, through imitating what they had seen at the kinemas. No particular picture or story was known to have inspired this boy, but it seemed probable that he got his obsession from that source. It will be generally agreed that no picture should be allowed to be displayed nor stories allowed to be printed and sold which are likely to be detrimental morally. The present censorship deals with offences against conventional respectability, but it is a more difficult problem to prevent films which may be of unfortunate influence to unstable minds. In this case the coroner regarded the lad as unbalanced by excitement, and a verdict of suicide during temporary insanity was returned. In Germany the censorship—abolished in the early days of the revolution—was recently reimposed. Films shown at performances to which young people under 18 are admitted are to be banned if they are considered likely to have a harmful effect on the moral, intellectual, or physical development of adolescents, or to cause excessive emotion. "Children under six are to be excluded from all performances" is the concluding sentence in an interesting note from the *Times* Correspondent in Berlin.

AN APPEAL FOR HOMELESS CHILDREN.

IN connexion with the Founder's Day celebrations Dr. Barnardo's Homes, which will be held on June 2 Barkingside, Essex, an appeal is being made for half-c "to feed the largest family in the world." Like all cha institutions the financial needs of Dr. Barnardo's have increased heavily in consequence of the war, an 7300 children to feed the responsibility of the manag is consequently very great. These homes have responsible for rescuing something like 89,000 ho children, and during the war nearly 11,000 Barnard were fighting in the navy or army. Half-crowns sh sent to the honorary director, 18 to 26, Stepney-cau London, E. 1.

THE EXTRA PHARMACOPŒIA OF MARTIND AND WESTCOTT.

THE new edition, published this week by H. K. Le Co., Ltd., of Vol. I. of the Extra Pharmacopœia by Mar and Westcott will be welcomed because since the las of five years ago much has happened in pharma pharmacology, and considerable additions and alte have been called for consistent with the well-known d ments arising out of the great war. We understan Vol. II., dealing mainly with analytical, bacteriologi laboratory questions generally, will be issued shortl new issue is remarkably up to date, summarising n the altered position of affairs in many directions of i to the consultant and general practitioner, wh position of the pharmacist, particularly in regard manufacture of those medicaments the supply of hitherto was from abroad is fully set out. There are i ing features in this new edition which invite later co The bibliography relating to the records of exam treatment published in medical journals is thorough and alone affords a valuable source of reference to men.

THE Gloucestershire Branch of the British Re Society has presented to the county their V.A. pital, Standish House, for the treatment of tub patients. Ex-Service men are to have preference ov candidates for admission.

THE Students of the Royal Free Hospi arranging a fair, to be held at the hospital on July 10 of the Hospital Appeal Fund. There will be various en ments, including a Thé Chantant, and stalls for th garden and dairy produce, lingerie, jumpers, and ho ware. Any offers of help will be most gratefully r and should be sent to Miss Longbottom at the Ro Hospital, Gray's Inn-road, London, W.C. 1.
